

The University of Toronto
Chemical Library

Presented
to
The University of Toronto Library
by
William Lash Miller, B.A., M.A., D.C., Ph.D.
Professor Emeritus of Physical Chemistry
for
A Departmental Library to be under
the control of the Professor of
Chemistry according to the conditions
set out in a letter from the Librarian
of the University dated March 21st
1938.

Digitized by the Internet Archive

THE SOCIETY OF CHEMICAL INDUSTRY

LIST OF PAPERS PRESENTED TO THE SOCIETY & PUBLISHED IN THE TRANSACTIONS DURING 1920

N.B.—The words within () indicate the Section or Group of the Society (if any) before which the paper was read and the issue of the Journal in which it appears.

	PAGE		PAGE
Aida, M. Determination of minute quantities of petroleum spirit in vegetable oils. (June 15)	152T	Butler, G. S., and H. B. Dunncliff. The estimation of alcohol in mixtures of alcohol, sulphuric acid, and water. (May 31) ..	146T
Alliott, E. A. Recessed plate and plate and frame filter-presses: their construction and use. (Annual Meeting, Aug. 31) ..	261T	Callan, T., J. A. R. Henderson, and N. Strafford. The estimation of the nitro group in aromatic organic compounds. (Manchester, Apr. 15)	86T
Andrews, A. C. P. <i>See</i> Read, J.	289T	Campbell, D. F. Recent developments of the electric furnace in Great Britain. (Annual Meeting, July 31)	224T
Anfilogoff, N. A. The handling of petroleum in bulk at Thames Haven. (Chemical Engineering Group, May 31)	138T	Challenger, F. <i>See</i> Frankland, P. F. 256T, 313T	
Ardern, E. The activated sludge process of sewage purification—large scale operation. (Manchester, Mar. 15)	60T	Chulow, F. S., and C. W. Taylor. The consistency of greases. (Aug. 31)	291T
Armstrong, E. F., and T. P. Hilditch. Catalytic actions at solid surfaces: some factors controlling the rate of hydrogenation of ethyl-ene compounds in presence of nickel. (Liverpool, May 15)	120T	Collins, S. H., and A. Spiller. Sugar in oat straw and cattle foods. (Mar. 15)	66T
Atkin, W. R., and W. E. Palmer. Determination of alkalinity in tannery lime liquors. (Yorkshire, May 31)	145T	<i>Erratum</i>	82T
Atkinson, H. M. An air-oven thermo-regulator. (Aug. 31)	298T	Colman, H. G. The estimation of paraffins in commercial toluol. (Feb. 28)	50T
Bailey, G. H. The rate of corrosion of aluminium. (Edinburgh, May 15)	118T	Crow, H. W. Method of transporting and distributing liquids about a factory. (Chemical Engineering Group, May 31) ..	144T
Barker, M. F. <i>See</i> Fox, J. J.	169T	Curtis, R., and F. D. Miles. The "heat-rise" method of testing sulphuric acid and oleum. (Mar. 15)	64T
Barrett, F. L. A new test for detection of ligneous impurities in cotton and cotton waste for nitration purposes. (Mar. 31) ..	81T	Dawson, H. M. Some observations on the "springing" of "carbolate," and the recovery of phenol from the resulting aqueous liquor. (Yorkshire, June 15)	151T
Bhatnagar, S. S., and W. E. Garner. The effect of addition of certain fatty acids on the interfacial tension between B.P. paraffin oil and mercury. (July 15) ..	185T	Desch, C. H. Some properties of 60:40 brass. (Annual Meeting, July 31)	216T
Bostock, B. R. <i>See</i> Knecht, E.	163T	De Vries, O. The "slope" or "type" of the rubber stress-strain curve. (Sept. 30) ..	308T
Bramwell, B. Design of mechanical filters. (Annual Meeting, July 31)	232T	De Waele, A. Consideration of some factors affecting the oxygen-absorption of linseed oil. (Feb. 28)	48T
Brazier, S. A. <i>See</i> Twiss, D. F. .. 125T, 155T		Donnan, F. G., and I. Masson. The theory of gas scrubbing towers with internal packing. (London, July 31)	236T
Brenchley, W. E., and E. H. Richards. The fertilising value of sewage sludges. (London, July 15)	177T	Dunncliff, H. B. <i>See</i> Butler, G. S.	146T
Brockbank, C. J. Manufacture of artificial abrasives in the electric furnace. (Birmingham, Feb. 28)	41T	Edwards, K. B., and G. A. Freak. Notes on the United States Government method of determining phenols in sheep dips. (Dec. 15)	326T
Brown, J. C. Notes on tungsten ore deposits in Burma. (Newcastle, Feb. 28)	44T	Faber, H. B. Industrial filtration. (American, Feb. 16)	21T

	PAGE		PAGE
Fawsitt, C. E. The action of concentrated sulphuric acid on iron. Part III. (May 31)	147T	Jones, W. J. <i>See</i> Sanderson, W. J. . . .	8T
Fox, J. J., and M. F. Barker. The analysis and composition of cresylic acid. (June 30)	169T	Joseph, A. F. Change of refractive indices of fixed oils with temperature. (Mar. 15) . . .	66T
and A. J. H. Gauge. Note on the determination of tar acids in drainage from tarred roads. (Aug. 16)	260T	and F. J. Martin. A note on an explosion during the separation of potassium by the perchlorate method. (Apr. 15)	94T
Fowles, S. H. <i>See</i> Hewson, G. W.	211T	A preliminary account of the chemistry of the Nile sudd. (Apr. 15)	91T
Frankland, P. F., and F. H. Garner. The preparation of picryl chloride by nitration of 1-chloro-2,4-dinitrobenzene. (London, Aug. 16)	257T	Knapp, A. W. <i>See</i> Liverseege, J. F. . . .	27T
F. Challenger, and D. Webster. The preparation of thiocarbonyl tetrachloride (London, Aug. 16)	256T	Knecht, E., and B. R. Bostock. The neutral hydrolysis of guncotton, with a note on the alkaline hydrolysis of guncotton. (Manchester, June 30)	163T
F. H. Garner, F. Challenger, and D. Webster. The preparation of thiophosgene from thiocarbonyl tetrachloride. (Oct. 30) . .	313T	Lane, K. W., and O. F. Lubatti. A rapid method of estimating water in crude camphor. (Feb. 28)	50T
Freak, G. A. <i>See</i> Edwards, K. B.	326T	Lantsberry, F. C. A. H., and R. A. Page. The solidification points of mixtures of metallic chlorides. (Birmingham, Feb. 28) . .	37T
Garner, F. H. <i>See</i> Frankland, P. F.	257T, 313T	Levinstein, H. The dyestuff industry. (London, Dec. 15)	317T
Garner, W. E. A metal-glass tap. (Dec. 31) .	347T	Lewis, E. The estimation of paraffins in commercial toluol. (Feb. 28)	50T
<i>See</i> Bhatnagar, S. S.	185T	Liverseege, J. F., and A. W. Knapp. The action of water on lead. (Birmingham, Feb. 16)	27T
Gauge, A. J. H. <i>See</i> Fox, J. J.	260T	Lowry, T. M., and F. C. Hemmings. The properties of powders. Part I. The eaking of salts. (London, Apr. 30) . .	101T
Gee, W. J. A new process of centrifugal filtration. (Annual Meeting, Aug. 16) . .	255T	and S. Wilding. A note on the setting of dental cements. (London, Apr. 30) . .	110T
Ghose, T. P. <i>See</i> Simonsen, J. L.	296T	Lubatti, O. F. A rapid method of estimating lead in cassia oil. (Feb. 16)	35T
Gibson, W. H., and R. McCall. The viscosity of solutions of nitrocellulose in ether-alcohol. (June 30)	172T	<i>See</i> Lane, K. W.	50T
Green, S. J. <i>See</i> Price, T. S.	98T	McCall, R. <i>See</i> Gibson, W. H.	172T
Grounds, A. <i>See</i> Sinnatt, F. S.	83T	Marshall, A. The detonation of hollow charges. (Feb. 16)	35T
Haddon, C. L. The setting of calcium sulphate cements. (Newcastle, June 30)	165T	Martin, F. J. The distribution of enzymes and proteins in the endosperm of the wheat berry. (Dec. 15 and 31)	327T, 348T
Hall, E. H. The estimation of nickel in steels by direct titration. (July 31)	253T	The properties affecting strength in wheaten flour. (July 31)	246T
Hall, G. F. <i>See</i> Richmond, H. D.	80T	<i>See</i> Joseph, A. F.	91T, 94T
Hatschek, E. The principles of technical filtration. (Annual Meeting, July 31) . .	226T	Masfarand, S. Distillation plant, with special reference to the rectification of alcohol, acetaldehyde, and other volatile products and continuous ether manufacturing plant. (Manchester, Sept. 15)	299T
Hayhurst, W. Pumping acids or other corrosive liquids, with particular reference to the armoured "Ceratherm" centrifugal pump. (Chemical Engineering Group, May 31)	145T	Masson, I. <i>See</i> Donnan, F. G.	236T
Hemmings, F. C. <i>See</i> Lowry, T. M.	101T	Maxted, E. B. Catalysis from an industrial standpoint. (Birmingham, Apr. 30) . .	95T
Henderson, J. A. R. <i>See</i> Callan, T.	86T	Menzies, S. H. The Sharples "super-centrifuge." (Annual Meeting, July 31) . .	231T
Henning, A. Technical applications of ethyl chloride. (London, Jan. 15)	1T	Miles, F. D. <i>See</i> Curtis, R.	64T
Hewson, G. W., and S. H. Fowles. The more economical utilisation of coke-oven and blast-furnace gases for heating and power. (Annual Meeting, July 31)	211T	Moore, B. <i>See</i> Sinnatt, F. S.	72T
Hilditch, T. P. <i>See</i> Armstrong, E. F. . . .	120T	Moore, H. A new instrument for measuring vapour tension. (Manchester, Mar. 31) .	78T
Hornby, A. J. W. Pectins in various plants. (Newcastle, July 31)	246T	Morrell, R. S. Catalysis applied to the oxidation of oils. (Birmingham, June 30) . .	153T
Howarth, G. B. A graphical method for the interpretation of flue-gas analyses. (Yorkshire, Dec. 31)	329T	Musgrave, A. E. Sodium peroxide fusions. (Nottingham, Mar. 31)	80T
Howson, C. W. H. <i>See</i> Twiss, D. F.	287T	Myers, J. E., and H. Stephen. Synthesis of $\beta\beta'$ -dichlorodiethyl sulphide (mustard gas). (Mar. 15)	65T
Illingworth, S. R. Researches on coal. Part I. The thermal decomposition of coal at low temperatures. Part II. An investigation of certain coking coals: a theory of coking. (Bristol, May 15 and 31)	111T, 133T	Nuttall, W. H. Wetting power and its relation to industry. (Glasgow, Mar. 31)	67T
Imison, M. <i>See</i> Wilson, L. P.	322T		
Jones, D. W. Chemical sheet lead. (Annual Meeting, July 31 and Aug. 16)	221T, 255T		
	Errata 255T		

	PAGE		PAGE	
Ormandy, W. R. The filtration of colloids. (Annual Meeting, July 31)	228T	Sinnatt, F. S., and B. Moore. A method of determining the relative temperatures of spontaneous ignition of solid fuels. (Manchester, Mar. 31)	72T	
O'Sullivan, J. The influence of temperature, concentration, duration of the mash, and slackness of the malt on the starch products of the extract of malt. (Birmingham, Feb. 16)	22T	Slator, A. The estimation of carbon dioxide and fermentable sugars. (Birmingham, June 15)	149T	
Page, R. A. See Lantsberry, F. C. A. II. ..	37T	Smith, E. W. By-products from coke-ovens. (Annual Meeting, July 31)	194T	
Palmer, W. E. See Atkin, W. R.	145T		Errata 255T	
Palmer, W. G. A laboratory apparatus for preparing electrolytic hydrogen. (Oct. 30)	316T	Southcombe, J. E. See Wells, H. M. ..	51T	
Pelmore, R. A. The Avamere "squeegee" pump. (Chemical Engineering Group, May 31)	144T	Speedy, A. The softening of plastic materials determined by the Widney resiliometer and expressed graphically. (Jan. 31) ..	18T	
Pickering, G. F. The commercial examination of sulphonated oils. (Yorkshire, Sept. 15)	305T		Erratum 36T	
Price, T. S., and S. J. Green. The preparation of cyanogen chloride on a large laboratory scale. (Birmingham, Apr. 30)	98T	Spiller, A. See Collins, S. H.	66T	
Prideaux, E. B. R. The deliquescence and drying of ammonium and alkali nitrates and a theory of the absorption of water vapour by mixed salts. (Nottingham, July 15)	182T	Stephen, H. See Myers, J. E.	65T	
Punter, R. A. Cotton cellulose. The application to industry of recent researches on its viscosity. (Dec. 31)	333T	Stevens, H. P. The preservation of vulcanised rubber. (July 31)	251T	
Read, J., and A. C. P. Andrews. Note on a Papuan natural petroleum. Part II. (Aug. 31)	289T	Stewart, R. A. The Marlen pump. (Chemical Engineering Group, May 31)	141T	
Reavell, J. A. The elevation of acids by the Kestner patent automatic elevator. (Chemical Engineering Group, May 31) ..	142T	Stewart, S. The detection of natural barytes in lithopone etc. (July 15)	188T	
Rees, W. J. The corrosion of coke-oven walls. (Annual Meeting, July 31)	197T	Strafford, N. See Callan, T.	86T	
Renwick, F. F. Photographic images—visible and invisible. (Hurter Memorial Lecture.) (Liverpool, June 30)	156T	Sturgeon, R. A. The "Sturgeon" self-discharging centrifuges for separating solids from liquids. (Annual Meeting, July 31)	230T	
Richards, E. H. See Brenehley, W. E. ..	177T	Taylor, C. W. See Chulow, F. S.	291T	
Richmond, H. D., and G. F. Hall. Note on the Reichert-Meissl-Polenske method. (Nottingham, Mar. 31)	80T	Thomas, R. The mechanism of the addition of hydrogen to unsaturated glycerides in the presence of finely-divided nickel. (Liverpool, Jan. 31)	10T	
Rogers, A. Industrial uses for the shark and porpoise. (American, Jan. 31)	9T	Trim, F. H. The use of the refractometer in ascertaining the purity of certain refined edible oils. (Sept. 30)	307T	
Rosenblum, E. I. Note on the determination of diastatic activity. (Oct. 30)	311T	Tungay, S. J. Centrifugal pumps for sulphuric and nitric acids. (Chemical Engineering Group, May 31)	143T	
Rowe, F. M. Hydrogenation in the naphthalene series. (Manchester, July 31)	241T	Twiss, D. F., and S. A. Brazier. The acceleration of vulcanisation. (May 15 and June 30)	125T, 155T	
Salway, A. H. A contribution to the theory of polymerisation in fatty oils. (Dec. 15)	324T		and C. W. H. Howson. The acceleration of vulcanisation. Part II. (Aug. 31) ..	287T
Sanderson, W. J., and W. J. Jones. The estimation of aniline in commercial anilines. (Jan. 15)	8T	Ward, W. A. Modern by-product coke-oven construction. (Annual Meeting, July 31)	198T	
Schwes, F. The vapour pressure of arsenious oxide in sulphuric acid solutions. (Feb. 16)	33T	Webster, D. See Frankland, P. F. ..	256T, 313T	
Sen-Gupta, N. N. A study of the fruit of <i>Schleichera trijuga</i> , with special reference to the generation of hydrocyanic acid in the seed. (Newcastle, Apr. 15) ..	88T	Wells, H. M., and J. E. Southcombe. The theory and practice of lubrication: the "germ" process. (London, Mar. 15) ..	51T	
Silvester, W. A. The rectified petroleum spirit from the toluene-petrol fraction of Borneo petroleum, with a note on laboratory fractionating columns. (July 15) ..	187T	West, J. H. General types of pumping machinery for chemical works. (Chemical Engineering Group, May 31)	139T	
Simonsen, J. L., and T. P. Ghose. The distillation of camphor in India. (Aug. 31) ..	296T	Weyman, G. A comparative method of determining the heat of carbonisation of coal. (Newcastle, June 30)	168T	
Sinnatt, F. S., and A. Grounds. A new characteristic for coal: the agglutinating power curve. (Manchester, Apr. 15)	83T	Wilding, S. See Lowry, T. M.	110T	
		Williams, A. M. The depolarisation by oxygen of a voltaic cell. (Edinburgh, Aug. 31) ..	285T	
		Wilson, L. P. Catalytic action in the oxidation of cellulose. (Birmingham, July 15) ..	177T	
			and M. Imison. The dyeing of artificial silk. (Dec. 15)	322T
		Wright, H. E. Coke-oven gas for town supply. (Annual Meeting, July 31)	214T	
		Young, W. Calculations involved in the preparation of acid mixtures used in the manufacture of nitrocellon. (Oct. 30) ..	315T	

Journal of the Society of Chemical Industry

Vol. XXXIX. 1920

Name Index

N.B.—The Review, Transactions, and Abstracts Sections of the Journal are vaged separately and are indicated by the letters R, T, and A respectively following the number of the page.

The letter (P) indicates that the matter referred to is a patent.

An asterisk appended to the number of a page indicates that the title only of an article is given, or in the case of patents, either the title only or the title and a reference to a previous patent.

The titles of new books are given within quotation marks.

Subject Index

N.B.—The Review, Transactions, and Abstracts Sections of the Journal are paged separately and are indicated by the letters R, T, and A respectively following the number of the page.

The letter (P) indicates that the matter referred to is a patent.

An asterisk appended to the number of a page indicates that the title only of an article is given, or in the case of patents, either the title only or the title and a reference to a previous patent.

Aldol condensation and formation of resin by action of dilute alkalis on —, Hammersen	764A		Formation of butyl alcohol and — by fermentation of starch by <i>Bac. granulobacter pectinovorum</i> . Speakman	381A	
Catalyst for manufacture of — from acetylene, and process of regenerating it. (P) Soc. des Acières et Forges de Firminy	582A		Ignition of mixtures of air, alcohol, and — in contact with heated surfaces. White and Price	95A	
Conversion of acetylene into —, Neumann and Schneider	639A		Intermediate substances produced in fermentation method for preparation of <i>n</i> -butyl alcohol and —, Reilly and others	421A	
Correlative formation of glycerol and — by scission of sugar. Neuberg and Reinforth	76A		Losses in preparation of — by distillation of acetate of lime. Goodwin and Sterne	396A	
Detection of — in alcoholic fermentation. Neuberg	276A		Manufacture of —:		
Determination of — in paraldehyde. Stüwe	764A		(P) Matheson	312A	
Distillation plant with special reference to rectification of —, Maseraud	299T		(P) Rappaport	222A	
Emanation of — from ripe apples. Power and Chesnut	609A		Manufacture of — from acetic acid. (P) Bayer und Co.	765A	
Formation of — by certain pentose-fermenting bacteria. Peterson and Fred	830A		Manufacture of carbonic acid and —, (P) Soc. Adoo. Acières et Forges de Firminy	44A	
Hydrogenation of — in presence of finely-divided metals. Armstrong and Hilditch	466A		Manufacture of formaldehyde, methyl alcohol, methyl formate and — by dry distillation of formates. (P) Hofmann	313A	
Manufacture of acetic acid from —, (P) Verein für Chem. Ind. in Mainz	426A		Micro-method for estimation of —, Richter-Quittner	206A	
Manufacture of — from acetylene			Purification of —, Duclaux and Lanzenberg	764A	
(P) Guyot, and Comp. Prod. Chlm. d'Alais et de la Camargue	583A*		Seed-culture methods in production of butyl alcohol and — by fermentation. Speakman	555A	
(P) Konsort. für Elektrochem. Ind.	427A		Acetoneglycerol and its applicability to preparation of pure α -glycerides. Fischer and Pfähler	790A	
Manufacture of ethyl acetate from —, (P) Konsortium für Elektrochem. Ind.	83A		Acetyl value of fats; Errors in determination of — and their remedy. Grün	33A	
Mode of pyrogenic decomposition, at high temperatures, of —, Peytral	206A		Acetylcellulose. <i>See</i> Cellulose acetate.		
Acetates; Determination of acetic acid in —, Pickett	585A				
Manufacture of — from carbohydrates. (P) Randall, and Industrial Chemical Co.	783A				
Recovery of acetic acid and manufacture of —, (P) Matheson	206A				
Systematic detection of —, Curtman and others	467A				

	PAGE
Acetylene: Action of — on arsenic trichloride. Dafert ..	19A
Action of nitric acid on —. Orton and McKie ..	384A
Catalyst for manufacture of acetaldehyde from — and process of regenerating it. (P) Soc. des Acieries et Forges de Firminy ..	582A
Catalytic process for preparation of acetic acid from —. (P) Soc. des Acieries et Forges de Firminy ..	704A
Combustion of — in motors. Haber ..	621A
condensations; Pyrogenic —. Meyer and Taeger ..	565A
Conversion of — into acetaldehyde and acetic acid. Neumann and Schneider ..	639A
Estimation of — in coal gas and air. Arnold and others ..	509A
Filling for tanks or the like intended for storage of —. (P) Särnmark ..	290A
Gas-analytical separation of ethylene, benzene, and —. Treadwell and Tauber ..	4A
gas and the like; Solvent for —. (P) Smith and others ..	326A
Manufacture of acetaldehyde from —. (P) Guyot, and Comp. Prod. Chim. d'Alais et de la Camargue ..	583A*
(P) Konsortium für Elektrochem. Ind. ..	427A
Porous charges for containers for storage of —. (P) Pinteb A.-G. ..	684A
Preparation of glyoxal by action of ozone on —. Wohl and Brännig ..	279A
Volumetric estimation of —. Willstätter and Masch- mann ..	509A
Acetylene dichloride; Antiseptic action of —. Salkowski ..	702A
Acetylmethylcarbinol; Specific reaction of —. Lemoigne ..	203A
Acetylnitrocellulose. Oddo ..	12A
Acetylsalicylic acid. Ramsay ..	134A
Determination of free acetic acid in —. Smith ..	610A
Melting point of —. Cappelli ..	801A
Preparation of double compounds of caffeine with alkali salts of —. (P) Wülfing ..	135A
Purification of —. (P) Hibbert, and Commercial Research Co. ..	44A
Acetylsalicylic acid chloride and cholic acid; Manufacture of a compound of —. (P) Riedel A.-G. ..	44A
Acid baths for treating wire. (P) Oates and Green, Ltd., and Ashton ..	196A*
bromides; Use of oxalyl bromide for producing —. Adams and Ulich ..	348A
chlorides; Use of 1,2-dichlorovinyl ethyl ether for pro- duction of organic —. Crompton and Vander- stichele ..	110R
chlorides; Use of oxalyl chloride for producing —. Adams and Ulich ..	348A
function; Indication of — and its determination. Kolthoff ..	837A
industry; Use of Raschig's rings in the —. Schellhaass mixed; Calculations involved in preparation of — used in manufacture of nitrocellulose. Young ..	315T
-proof alloys; Manufacture of —. (P) Rossi ..	787A
-proof cement; Manufacture of moulded articles from —, (P) Windsor-Richards ..	821A
-proof coatings for concrete surfaces; Bituminous — — Oil-proof and —. (P) Jones ..	664A
-resisting alloy; Aluminium-iron bronze as —. Kowalke ..	507A
-resisting alloys. (P) Clement, and Cleveland Brass Manufacturing Co. ..	158A
-resisting iron silicon alloys; Preventing precipitation of graphite in manufacture of —. (P) Maschinen- fabr. Esslingen ..	520A
-resisting material impervious to water; Manufacture of —. (P) Frenz ..	694A
-resisting metals. Matignon ..	659A
-resisting steel alloys. (P) Strass, and Chem. Foun- dation, Inc. ..	158A
-resisting ware; Substitute for hard lead for —. (P) Stockmeyer and Hanemann ..	457A*
sludge obtained in refining petroleum and shale oils; Utilisation of asphaltic base —. Baskerville ..	161A
sludge produced in purification of benzol; Recovery of benzol and its homologues from —. (P) Stephenson ..	570A
solutions, e.g., chrome tanning liquors; Contrasting effects of chlorides and sulphates on hydrogen ion concentration of —. Thomas and Baldwin ..	182A
Acidimetry; Ferrous sulphide as indicator in —. Houben ..	777A
Acidity; Determination of — e.g., in worts, and titration in stages. Liens ..	123A
of sulphite liquor; Apparatus for regulating — and like purposes. (P) Crandon, and Crandon Manu- facturing Co. ..	85A
of worts, beers, and other similar liquids; Determina- tion of —. Windisch and Dietrich ..	669A
Acids, aliphatic; Preparation of — by catalytic oxidation of primary alcohols. Mailhe and De Godon ..	513A
carboxylic; Converting — into aldehydes. Sonn and Müller ..	312A
carboxylic; Manufacture of hydrocarbons and alkali salts of high molecular —. (P) Albrecht and others ..	82A
Centrifugal pumps for —. (P) Union Espagnole de Fabr. d'Engrais, de Prod. Chim., et de Super- phosphates ..	151A
Conductometric titration of —. Kolthoff ..	711A

	PAGE
Acids—continued.	
Conductometric titration of combined weak — in salts. Kolthoff ..	558A
Elevating — by the Kestner patent automatic elevator. Reavell ..	142T
fatty; Anhydrides of higher aliphatic — ..	789A
Holdre and Smolkus ..	789A
Holdre and Tacke ..	789A
fatty; Capillary active and inactive modifications of higher — and their relation to titrations with capillary active substances as indicators. Wind- isch and Dietrich ..	613A
fatty; Catalytic decomposition of — by carbon. Senderens and Aboulenc ..	425A
fatty; Deodorising —. (P) Ver. Chem. Werke A.-G., and Lüdecke ..	376A
fatty; Determination of oxidised — in olive oils extracted with carbon bisulphide. Stadlinger ..	668A
fatty; Effect of addition of — on interfacial tension between paraffin oil and mercury. Bhatnagar and Garner ..	185T
fatty; Extraction of higher — from wood-, lignite-, or peat-tar. (P) Börnstein ..	359A
fatty; Extraction of higher — from wood-tar. (P) Börnstein ..	57A
fatty; Heat-balance of distillation plant for recovery of — from cottonseed foots. Alsberg ..	458A
fatty; Hydrogenation —. (P) Radisson and others ..	756A*
Fatty — from lignite tar oils ..	186R
fatty; Manufacture of —. (P) Harries and others ..	765A
fatty; Manufacture of — from low-temperature lignite tar oils. Harries ..	397A
fatty; Nephelometric values of higher —. Csonka ..	417A
Fatty — obtained by oxidation of paraffins. Fischer and Schneider ..	521A
fatty; Oxidation of paraffins to —. Grün ..	521A
fatty; Polymerisation of unsaturated — at low temperature. (P) Nordisker Fabr. De-No-Fa Aktieselskap ..	697A
fatty; Preparation of — for soap from petroleum oil fractions of high molecular weight. Ubbelohde and Eisenstein ..	459A
fatty; Production of — by catalytic oxidation of hydrocarbons. Franek ..	395A
fatty; Role of — in lubrication ..	47R
fatty; Separation of highly unsaturated — in fish oils. Tsujimoto ..	825A
fatty; Splitting fats and oils for manufacture of glycerin and —. (P) Twitchell Process Co. ..	697A*
fatty; Synthesis of — from paraffin wax and other petroleum fractions. Löfl ..	604A
fatty; Turbidity temperature of —. Parkes ..	143R
fatty; Volatility with steam of lower — in dilute aqueous solution. Witzmann ..	134A
Formation of — by moulds and yeasts. Boas and Leberle ..	168A
Iodometric estimation of —. Kolthoff ..	175A
Manufacture of —. (P) Chaplin ..	189A
organic; Apparatus for electrolytic decomposition of — at low temperature and with small volumes of liquid. Henrich and Schenk ..	162A
organic; Catalytic preparation of — from nitriles. Mailhe ..	610A
organic; Dissociation constants of — as means for their identification. Kolthoff ..	703A
organic; Extraction of — from wood-, lignite-, or peat-tar. (P) Börnstein ..	359A
organic; Extraction of — from wood-tar. (P) Börnstein ..	57A
organic; Identification of — as <i>p</i> -halogenphenacyl esters. Judefeld and Reid ..	501A
organic; Identification of — by phenacyl bromide; Injurious action of latter on the skin. Cox ..	832A
organic; Manufacture of —. (P) Moest and others ..	501A
organic; Manufacture of water-soluble alkaline-earth salts of —. (P) Herzfeld and Léhart ..	467A
organic; Rapid volumetric determination of —. Foreman ..	613A
Pumping —, with particular reference to the armoured Cerathermi centrifugal pump. Hayhurst ..	145T
Simultaneous conductometric titration of different —. Kolthoff ..	530A
Sterilising power of —. Aubel ..	424A
Titration of mixed — by conductivity methods. Kolthoff ..	316A
Titration of — using surface-active higher fatty acids as indicators. Windisch and Dietrich ..	138A
volatile; Determination of — in fermentation products. Hinard ..	669A
volatile fatty; Influence of electrolytic dissociation on distillation in steam of —. Reilly and Hickin- bottom ..	708A
waste; Apparatus for recovery of nitric and sulphuric acids from —. (P) Baer ..	748A
waste; Recovery of — from mineral oil refining. Kolbe ..	438A
weak; Titration of — with weak bases. Kolthoff ..	706A
Acrolein; Preparation of —. Moureu and Lapape ..	42A
Reaction of —. Tsalapatanis ..	425A
Stabilisation of —. Moureu and Lapape ..	42A
Stabilisation of —. Compounds acting as stabilisers against formation of desacryl (insoluble resin). Moureu and others ..	82A

	PAGE		PAGE
Acrolein— <i>continued</i> .		Air— <i>continued</i> .	
Stabilising action on — of substances with a phenolic group. Mourou and others	173A	Liquefaction and separation of —. (P) Mewes ..	323A
Actinometers and the like. (P) Hargreaves	471A	liquid; Production and use of — for blasting. Diederichs ..	315A
Adhesive compositions, especially for waterproofing fabrics and rendering them impermeable to gases. (P) Soc. Anon. Etabl. Hutchinson	482A	liquid; Rectification of —:	688A
compositions; Improving —. (P) Sarason	309A	Barbet	489A
compositions; Manufacture of —. (P) Alexander ..	795A	(P) Barbet et Fils et Cie.	688A
pastes; Manufacture of —. (P) Veredlungsges. f. Nahrungs-u. Futtermittel	275A	liquid; Vessels for transport and handling of —. Moser	51A
Adhesives for articles made of cellulose derivatives. (P) Bayer and Co.	361A, 719A	ovens; Thermo-regulator for —. Atkinson	208T
Manufacture of —:		pollution by smoke; Effects of — and its prevention. Cohen	284R
(P) O'Gorman and Schryver	419A	Purification of —. (P) Everitt	563A
(P) Wallasch	759A	Purification of expired —. (P) Spator	761A
Manufacture of — from cellulose waste lyes. (P) Claas	719A	Separating — into its constituents. (P) Ges. f. Linde's Elsmaschinen A.-G.	545A, 597A*
Manufacture of flexible — unaffected by hot water. (P) Hoffmann	469A	Separation of — into oxygen and nitrogen. Norton	721A
Manufacture of — from lignite. (P) Gerdes	759A	supply for blast-furnaces; Heating the —. (P) Comp. des Forges et Acieries de la Marine et d'Homécourt	238A
Manufacture of — from starch. (P) Bloede	202A	Vitiation of — by storage of tobacco and other vegetable substances. Frederick	799A
Manufacture of — from sulphite-cellulose waste lyes. (P) Hüttenes	309A	Aircraft; Fireproofing for —. (P) Bradley, and Aircraft Fireproofing Corporation	13A, 757A*
Adipic acid esters; Manufacture of —. (P) Bayer und Co.	427A	Manufacture of fabrics for —:	186A*
Adrenaline; Colorimetric determination of —. Scoville	673A	(P) Feary	13A
Manufacture of —. (P) Nagai	43A	(P) Sage and Co., and Feary	113R
Absorbed substances; Separation of —. (P) Schwerin, and Ges. für Elektro-Osmose	145A*	Alaska; Mineral output of — in 1919	
Absorbing materials; Density of various —. McLean ..	540A	Alberta. <i>See under</i> Canada.	
Adsorption. Berzeller	189A	Albumin; Acid—	702A
Emulsification by — at n nitrobenzene-water interface. Sheppard	100A	Manufacture of a colloidal solution, neutral to the taste, from vegetable —. (P) N. V. Jurgens Vereenigde Fabr.	204A
of gases by carbonised lignite. McLean	543A	Albumins; Behaviour of — towards the electric current, and isolation of pure antitoxic albumin from diphtheric serum by electro-osmosis. Ruppel	557A
of gases by charcoal; Effect of pressure on —. Pickles	543A	Albumoses; Histamine and a histamine-like substance as decomposition products of —. Nagayama	673A
Reactivity and — in heterogeneous catalysis. Rideal of surface-active substances by various adsorbents. Michaelis and Rona	91A, 205A	Alcohol, absolute; Manufacture of —. (P) Frankforter	701A
of vapours on charcoal; Heat of —. Lamb and Coolidge	557A	absorbed in sulphuric acid; Recovery of —. (P) Herrmann	765A
Acrating sewage and other foul liquids; Apparatus for —. (P) Ames	525A	and aniline; Catalysts which promote reaction between —, Johnson and others	594A
sewage and other impure liquids. (P) Stott and Jones ..	557A*	from coke-oven gas	308R
Aeroplane propellers; Fabric coated with "bakelite" for	338R	Combustible mass of kieselguhr soaked with —. (P) Von Schütz	358A
Aeroplanes; Flexible fireproof material for —. (P) Feary	686A	Dehydrogenation of ethyl — in presence of finely-divided metals. Armstrong and Hilditch	466A
Material and dopes for planes of —. Fuchs	292A	denaturants. Dobble	86R
Africa; Phosphate production in French North	438R	denatured; Detection of — in spirits. Haase	796A
Agar; Action of radium radiation on —. Fernan	554A	denatured; Manufacture of —. (P) Pascal	426A
gels containing silver nitrate; Penetration of sodium chloride into —. Stiles	274A	Denatured — in U.S.A.	337R
Ageing machines. (P) Calico Printers' Assoc., and others	154A	Denaturing — at the distilleries in Canada	379R
Agitating apparatus; Decanting and —. (P) Pettis ..	564A*	and its derivatives; Fixation of ethylene present in coke-oven gas as —. Bury	94A
liquid or semi-liquid materials; Apparatus for mixing, circulating, and —. (P) Coles, and Allen and Co. ..	144A	Detection of water in —. Henle	501A
liquids by means of a magnetic field. (P) Meyer	394A	Determination of — in beverages and the like. (P) Dehn	352A
and/or mixing machines. (P) Brinjes, and Goodwin, Ltd., and Harris	564A	Determination of composition of mixtures of water and — by electrical conductivity measurements. Kolthoff	203A
Agitators. (P) Sayre	256A	Determination of — in mixtures of alcohol, sulphuric acid, and water. Butler and Dunnicliff	146T
Agricultural Journal of Union of South Africa; Re-appearance of —	219R	Differentiation of methyl alcohol and ethyl —:	38A

Aluminium iron phosphates; Utilisation of — Stanley	344A
nitrate; Manufacture of — (P) Hood	689A
nitride; Furnace for manufacture of — (P) Herman	570A
nitride and the like; Manufacture of — (P)	
Shoeld, and Armour Fertilizer Works	570A
nitride; Manufacture of —	
(P) Armour Fertilizer Works, and Shoeld	406A*
(P) Gerber	657A
oxide; Hydrous — Weiser	781A
phosphate; Soluble — Svanberg	19A
silicates; Treatment of naturally occurring — (P)	
Borchers	570A
sulphate; Manufacture of — free from iron, from	
clay. (P) Papierfabr. Köslin A.-G.	109A
sulphate; Rapid estimation of — in alum. Codwise	446A
Aluminosilicates; Decomposition of alkali — (P) Berge	544A
Aluminothemic reactions; Manufacture of ferrosilicic oxide	
suitable for — (P) Bredig and others	191A
Aluminous materials; Conversion of powdered — into	
granular form. (P) Hood	657A
materials; Purification of — (P) Hutchins	690A*
Alundum filtering crucibles; Use of — Englis	677A
Alunite; Process of treating — (P) Downs	489A
Utilisation of native — (P) Chappell	405A
Amalgam presses. (P) Cocks	823A
Amalgamators; Centrifugal — (P) Musser	492A*
Amalgams; Electro-endosmosis, and preparation of solid	
alkali — Frank and Withrow	455A
American Ceramic Society	131R
American Chemical Society	113R, 183R, 217R, 338R
American Petroleum Institute	14R
Amides of alkalis and alkaline-earth; Manufacture of —	
(P) Badische Anilin und Soda Fabrik	749A
of N-arylglycinearsonic acids. Jacobs and Heidelberger	41A
of N-arylglycinearsonic acids; Aromatic — Jacobs	
and Heidelberger	42A
Production of formic acid by yeast in media containing	
— Thomas	421A
Utilisation of — by yeast. Thomas	77A
Amines; Iodination of aromatic — by means of iodine	
and persulphate. Elbs and Volk	173A
Manufacture of aromatic — (P) Du Pont de	
Nemours and Co.	280A
Oxidation of — Goldschmidt	224A
Preparation of — by catalysis. Mailhe	466A
Substituting halogens for amino groups in aliphatic	
— (P) Chem. Fabr. Flora	385A
Sympathomimetic — Madinaveitia	526A
Aminoacetanilide; Preparation of — Hill and Kelsey	673A
Amino-acids in cane juice; Influence of — on sugar	
technology. Waterman and Van Ligten	794A
Determination of — by means of the hydrogen elec-	
trode. Tague	431A
Preparation of esters of — Foreman	277A
Rapid volumetric determination of — Foreman	613A
α-Amino-acids; Manufacture of complex silver salts of	
— (P) Napp	640A
2-Aminoanthraquinone; Manufacture of — (P) Fischer,	
and Geigy S. A.	442A*, 480A*
o-Aminocinnamylidene-quinaldine methiodide; Synthesis of	
— Mills and Evans	685A
Amino-derivatives of naphthalene; Sympathomimetic —	
Madinaveitia	526A
Aminohydrindencarboxylic acid; Manufacture of a phenyl-	
ated — (P) Chem. Werke Grenzach A.-G.	802A
Aminosulphonic acids; Manufacture of — (P) Traube	427A
Manufacture of tanning substances from N- and O-aryl-	
sulpho derivatives of aromatic — (P) Ges. f.	
Chem. Ind. in Basel	666A
o-Aminothiophenol; Action of — on ortho-quinones.	
Stahrfoss	225A
Aminotolulic acids; Alkamine esters of — and other similar	
compounds of such acids. (P) Wildman, and	
Parke, Davis, and Co.	426A

	PAGE
Ammonia; Advantages of synthesis of — at very high pressures. Claude	187A
Apparatus for catalytic preparation of nitrogen oxides from —. (P) Barth	782A
Apparatus for production of synthetic —: (P) Gardiner	334A
(P) General Chemical Co., and De Jahn	108A
Apparatus for purifying nitrogen-hydrogen mixtures prior to synthesis of —. (P) General Chemical Co., and De Jahn	589A
Catalyst for oxidation of —: (P) Mauchot and Haas	190A
Perley	187A
Catalytic oxidation of —: Neumann and Rose	264A
(P) Tallant	365A*
Catalytic production of nitrogen oxides from —. (P) Permutit A.-G.	688A
Catalytic synthesis of —. Guichard and others	362A
Colorimetric determination of — in water. Kalthoff	761A
coolers; Working of —. (P) Klönne	334A
Determination of — in the gases in the synthetic process. (P) Rideal and Tarrant	516A
Determination of — in oil and fat preparations, such as Turkey-red oil etc. Welwart	727A
Determination of — in soils. Matthews	308A
Determination of — in urine, serous liquids, and the oxidised liquid of the Kjeldahl method. Hahn and Kootz	735A
Direct recovery of — from distillation gases. (P) Plette, and Soc. Franco-Belge de Fours à Coke	814A*
Disposal of waste liquor in recovery of — from distillation gases. (P) Phoenix A.-G. für Bergbau u. Hüttenbetrieb	395A
Distillation of — in analysis. Davison	316A
Electrically heated bomb for synthesis of —. Davis and Bryan	401A
Equilibrium in the system ammonium thiocyanate — Foote and Hunter	265A
flame; Formation of free hydrogen in the reversed Müller	187A
Franco-German convention in connexion with production of synthetic	305R
gas; Action of very concentrated solutions of iodic acid on —. Deniges and Barlot	781A
gas equilibrium; Calculation of the —. Maurer	61A
gas; Iodic acid as microchemical reagent for gaseous —. Deniges	595A
German comments on Claude's process for synthetic production of —	114R
and the like; Manufacture of —. (P) Calvert	401A
Manufacture of —. (P) Haslup	110A*
Manufacture of — from ammoniacal liquor and milk of lime. (P) Otto and Co.	627A
Manufacture of ammonium salts from industrial gases containing —. (P) Chem. Fabr. Kalk	22A
Manufacture of anhydrous —. (P) Lowenstein	21A
Manufacture of — from atmospheric nitrogen. (P) General Chemical Co., and De Jahn	231A
manufacture; Claude process of synthetic	381R
Manufacture of combustible gas or coke and — from pent and the like. (P) Sauer	6A
Manufacture of — from crude ammoniacal liquor. (P) Piron	108A
Manufacture of — from crude calcium cyanamide. (P) Otto and Co.	448A
Manufacture of — from crude cyanides. (P) Metzger, and Air Reduction Co.	749A
Manufacture of — from cyanamide. (P) Brodtkorb, and Norsk Hydro-Elektrisk Kvaestofaktieskab	295A*
Manufacture of cyanides for preparation of —. (P) Thorsell and Lundén	190A
Manufacture of cyanogen and —. (P) Balfour-Guthrie Investment Co.	579A*
Manufacture of diacyanodiamide and — from crude calcium cyanamide. (P) Stickstoffwerke Ges.	404A
Manufacture of dry — from nitrolim. (P) Wiedemann	656A
Manufacture of formates and — from cyanides, ferrocyanides, and cyanised briquettes. Heise and Foote	362A
Manufacture of — from gas liquor. (P) Schuchardt	742A
Manufacture of mixtures of hydrogen and nitrogen by decomposition of —. Davis and Olmstead	362A
Manufacture of mixtures of nitrogen and hydrogen for synthesis of —: (P) Ellis and Lutkins	231A
(P) Gerfin and others	656A
(P) Harger	516A
Manufacture of nitric acid from —. (P) General Chemical Co., and De Jahn	748A
Manufacture of nitric oxide from —. (P) Bayer und Co.	64A
Manufacture of synthetic —: (P) Clancy, and Nitrogen Corp.	688A
(P) Claude, and L'Air Liquide	335A*
(P) Gardiner	231A
(P) Greenwood	231A, 488A, 688A
(P) Metzger	334A
(P) Rideal and Tarrant	516A
Material for use in operations with hydrogen under high pressure and at high temperatures, especially for catalytic preparation of —. (P) Badische Anilin u. Soda Fabrik	656A

and nitrogen; Variety of carbon formed in reaction between —, Remelé and Rassow .. 232A
Calcium carbonate; Grinding — (P) Ryan and Seaman .. 166A
carbonate; Natural — in relation to chemical composition, bacterial contents, and crop-producing power of very acid soils, Conner and Noyes .. 634A
carbonate; Reaction of liquids which are saturated with —, Bjerrum and Gjaldbæk .. 699A
chloride; Preventing volatilisation of ammoniacal nitrogen by means of —, Stutzer .. 37R
chloride; Solidification points of mixtures of sodium chloride, potassium chloride, and —, Lantsberry .. 174A
citrate; Purification of — (P) Golding and others .. 409A
compounds; Iodic acid as microchemical reagent for soluble and insoluble —, Deniges .. 488A
Calcium cyanamide; Apparatus for improving the grade of — (P) Cox, and American Cyanamid Co. .. 200A
Attempts to obtain crude — free from dust, Caro .. 74A
Calcium carbide content of crude —, Maly .. 265A
Calcium cyanide from —, Landis .. 201A
containing free lime; Granulating — (P) Thrane .. 579A
Continuous manufacture of crude — (P) Lang .. 488A
Calcium cyanamide—continued.
Decomposing crude — mixed with a liquid by means of carbon dioxide, (P) Zarinko .. 498A
Decomposition of crude — (P) Chem. Fabr. Kalk .. 488A
Determination of cyanamide and dicyanodiamide in —, Marquoyrol and others .. 553A
Determination of cyanamide nitrogen in crude —, Neubauer .. 704A
Electrically heating the reacting materials in manufacture of crude — (P) Novak .. 488A
Granulating — (P) Barbe .. 379A
Granulating — for use as fertiliser, (P) Saves .. 759A
Improvement of crude — for use as fertiliser, Baumann .. 275A
Influence of iron oxide and sodium chloride upon fertilising action of —, Leunermuann and Elmcke .. 75A
Influence of storage on nitrogen losses and nitrogen changes in crude —, Meyer and Gorkow .. 75A
Inorganic impurities in crude —, Baumann .. 379A
Manufacture of ammonia from —: .. 295A*
(P) Brodtkorb, and Norsk Hydro-Elektrisk Kvaeldstofkieselskab .. 418A
(P) Otto and Co. .. 404A
Manufacture of ammonia and dicyanodiamide from crude — (P) Stickstoffwerke Ges. .. 488A
Manufacture of crude —: .. 488A
(P) Duchemin .. 749A
(P) Novak .. 656A
Manufacture of cyanamide solutions from crude — (P) Dannel, and Elektrizitätswerk Lonza .. 599A
Manufacture of dry ammonia from — (P) Wiedemann .. 420A
Manufacture of Portland cement from waste product from decomposition of —, Baumann .. 191A
Means of emptying the furnace in manufacture of crude — (P) Dienemann .. 498A
oven, (P) Cox, and American Cyanamid Co. .. 818A
Physiological action of crude —, Siebner .. 382R
Preparation and properties of pure —, Kameyama .. 360R
production in Germany .. 401A
Production of non-dusty crude — .. 39R
Steam consumption in manufacture of ammonia from crude —, Baumann .. 166A
Use of — in case-hardening baths, Shimer .. 485A
Variety of carbon present in crude —, Remelé and Rassow .. 166A
as a vegetation factor, Linter .. 485A
Yields in manufacture of —, Pluvinaige .. 265A
Calcium cyanide from calcium cyanamide, Landis .. 232A
fluoride precipitate; Obtaining — (P) Chase, and National Carbon Co. .. 406A
hydride; Manufacture of — (P) Kiese-walter .. 230A
hydride; Some reactions of —, Reich and Serpek .. 503A
hydroxide; Carrying down of — by precipitates of ferric hydroxide, Toporescu .. 467A
hydroxide, *See also* Lime.
iodide; Manufacture of organic derivatives of — (P) Spitz .. 401A
nitrate; Determination of nitrogen in —, Platou .. 675A
oxalate; Manufacture of — (P) Dupont and Hanke .. 747A
oxide; Extraction of — from calcined magnesite, Duschak .. 626A
oxide; Manufacture of compact blocks of — from calcium hydroxide sludge, (P) Bayer and Co. .. 802A
oxide; Manufacture of colloidal preparations of amylo-dextrin and — (P) Lecinwerk Laves .. 201A
phosphate; Manufacture of di- —, and fertiliser produced therewith, (P) Sadtler .. 671A, 798A
phosphate; Recovering proteins, magnesium phosphate, and — from acid waste waters from maize steeping, (P) Gliesecke .. 107A
phosphates; Application of a physico-chemical method of analysis of precipitates to study of —, Jollibois .. 794A
phosphates; Mechanical treatment of tri- — (P) Comp. des Phosphates de Constantine .. 826A
saccharate; Coagulation of rubber latex with —, Stevens .. 758A
salts; Antagonistic action of — towards other salts in soils as measured by ammonification and nitrification, Greaves .. 698A
silicate; Effect of di- — on an acid soil, Hartwell and Pember .. 336A
Calcium sulphate cements; Setting of —, Haddon .. 165R
Effect of — on cement, Witt .. 497A
Effect of — on solubility of soils, McCool and Millar .. 401A
Formation of double salts of potassium sulphate and — at 100° C. Anderson and Nestell .. 364A
Manufacture of ammonium sulphate from — (P) Badische Anilin u. Soda Fabr. .. 488A
Manufacture of ammonium sulphate from gas-liquor and — (P) Otto and Co. .. 802A
Manufacture of colloidal preparations of amylo-dextrin and — (P) Lecinwerk Laves .. 364A
Manufacture of hydrogen sulphide from — (P) Beck .. 365A, 570A
Manufacture of sulphur from — (P) Badische Anilin u. Soda Fabr. .. 63A, 570A
Manufacture of sulphur oxides from — (P) Badische Anilin und Soda Fabr. .. 748A
Manufacture of sulphuric acid from — (P) Behrens

Civet; Adulteration of —. Nivière	763A
Clarification of salt solutions. (P) Krupp A.-G. Grusonwerk	658A
Clarifiers; Centrifugal —. (P) Del Valle	648A
Classifying. See Grading.	
Clay, acid; Acidity of Japanese —. Kobayashi	655A
Coagulation of — and protective action of humic acid. Odén	242A
Drying machines for —. (P) Irwin and Knowles	214A
Extraction of alumina from —. (P) Wildman	191A
Fusibility of mixtures of graphite ash and bond —. Long	628A
and the like; Mining or quarrying —. (P) Osmosis Co., and Highfield	65A
Manufacture of alumina from —. (P) Goldschmidt and others	820A*
Manufacture of aluminium sulphate, free from iron, from —. (P) Papierfabr. Köslin A.-G.	109A
Manufacture of crude sodium alum from —. (P) Linkmeyer	64A
Manufacture of dry-pressed bricks from —. (P) Chem. Lab. für Tonind. und Tonind.-Zeit. Seger und Kramer	784A
Moulding —. (P) Allen	451A*
Osmotic purification of —. Ormandy	234A
Preparation of — for shaping in the dry state. (P) Chem. Lab. f. Tonind. u. Tonind.-Zeit. Seger u. Krainer	690A
products; Kilns for burning —. (P) Webster	490A
Re-hydration of calcined —. Laird and Geller	24A
suspensions; Coagulation of —. Smith	423A
Testing — for concrete aggregates. Fuller	491A
Treatment of —: (P) Borchers	64A
(P) Feldenheimer	65A*
(P) Fleissner	722A
Treatment of — and manufacture of articles and materials therefrom. (P) Smith	658A
ware; Burning — in tunnel kilns. (P) Harrop	450A
Clays in British Columbia	272R
Classification of — on a ceramic basis. Watts	490A
Relations between chemical composition, microscopic structure, and ceramic qualities of —. Bertrand and Languine	110A
Ultramicroscopic examination of —. Alexander	628A
Cleaning compound. (P) Gorius and Hays	34A
material; Fibrous —. (P) Reils and Co.	15A, 227A
by means of aluminium hydroxide. (P) Buchner and polishing powder from cellulose hydrate. (P) Slaughter and others	756A
process: (P) Buchner	568A
(P) Horkenbach	376A, 459A
Clinker and the like; Plant for manufacture of —. (P) Atkins and Colquhoun	599A*
Cloth; Action of atmospheric influences on —: Grass	481A
Kertesz	481A
Wagner	512A
made from yarn treated with mineral oil; Washing —. (P) Pinagel, and Aachener Chem. Werke für Textilindustrie	154A
Clouds, artificial; Production of intense —. (P) Weiss and Verdier	469A*
<i>Clupea longiceps</i> ; Fatty oil of —. Menon	93R
<i>Cnicus Benedictus</i> seeds; Fatty oil of —. Ferenez	71A
Coal; Action of — on a photographic plate. Stokinson	357A
Agglutinant for conglomeration of —. (P) Irazusta	289A
Air-dried condition and hygroscopicity of fossil — in relation to numerical value of calorific power. Kempf	620A
analysis. Singatt	538A
Apparatus for analysis or determining volatile constituents of —. (P) Naito	642A
Apparatus for drying or cooling —. (P) Davis	436A
Apparatus for separating fine —. (P) Draper	54A*
Apparatus for washing —: (P) France	478A
(P) Habets and France	714A

lamps; Leading-in conductors for —. (P) Anderson, and General Electric Co. ..	291A
lamps; Mercury arc —. (P) Heraeus ..	566A
lamps; Mercury vapour —. (P) Cornu ..	511A*
lamps; Production of filaments for —. (P) General Electric Co. ..	593A*
primary batteries; Manufacture of alkaline gelatinous electrolytes for —. (P) Engle, and American Elementary Electric Co. ..	824A*
primary cells and storage batteries; Manufacture of tubular electrodes for —. (P) Svenska Ackumulator Aktiebolaget Jungner ..	727A*
storage-battery plates; Treatment of —. (P) Martin, and Philadelphia Storage Battery Co. ..	416A
storage cells. (P) Fery ..	304A
transformers and switchboards; Incombustible or difficultly combustible insulating liquids for —. (P) Grossmann ..	340A
welding. See under Welding.	
Electrical charge on diaphragms; Modifying the —. (P) Schwerin, and Elektro-Osmose A.-G. ..	162A*
classification of finely-divided material. (P) Schmidt, and International Precipitation Co. ..	393A
compounding of liquids with gases or other components, including carbonating of beverages. (P) Bloom ..	494A
conductivity of gases during chemical reactions; Constancy of —. Trautz and Henglein ..	403A
conductivity of metals and alloys at high temperature; Measurement of —. Haughton ..	216T
conductivity of mixtures of fused and solid salts. Sandonini ..	603A
conductivity of soda-lime silicate glass. Ambrogn ..	295A
conductivity; Use of — for determining composition of alcohol-water mixtures. Kolthoff ..	203A
conductor; Producing an alteration of structure of an — by heating during winding. (P) A.-G. Brown, Boveri, and Co. ..	458A
conductors; Leading-in —, e.g., for electric lamps. (P) Anderson, and General Electric Co. ..	291A
conductors; Manufacture of impregnating material for fibrous insulating covering of —. (P) Bruggemann ..	633A
deposition of particles from gases. (P) Lodge, and Lodge Fume Co. ..	711A
endosmose of molten sodium chloride into carbon. Ostwald ..	31A
energy; Transforming kinetic energy of gases into — and utilising latter for carrying out gas reactions. (P) Petersen ..	696A
equipment at works of Ebbw Vale Steel, Iron, and Coal Co., Ltd. Dixon ..	336R
heater for coal-tar naphtha distillation test. Hill and Chillas ..	397A
-heater resistance element. (P) Gardner and others ..	494A
heater for vapours or conducting gases. (P) Allgem. Elektrizitäts-Ges. ..	356A
heating apparatus for liquids; Liquid-tight insulated joints for —. (P) Bellaviti ..	54A*
heating of insulating or inflammable liquids. (P) Allgem. Elektrizitäts-Ges. ..	340A
insulating liquids for transformers and switchboards; Incombustible or difficultly combustible —. (P) Grossmann ..	340A
insulating material from coumarone-resin. (P) Wells, and Ellis-Foster Co. ..	340A
insulating material; Plastic —. (P) Motta and others ..	340A
insulating moulded articles; Manufacture of —. (P) Grünwald ..	272A
insulation (P) Elektro-Material Ges. ..	494A
insulators; Manufacture of moulded —. (P) Westinghouse Electric and Manufacturing Co. ..	374A
machines and transformers; Drying insulation for —. (P) A.-G. Brown, Boverie et Cie. ..	32A
mechanical filters; Continuous —. (P) Meston, and Research Corp. ..	355A
power. See under Power.	
precipitating system. (P) Chubb, and Westinghouse Electrical and Manufacturing Co. ..	648A
precipitation apparatus; Electrodes for use in —. (P) Siemens-Schuckertwerke Ges. ..	393A
precipitation; Device for — employing high-tension current. (P) Siemens-Schuckertwerke Ges. ..	437A
precipitation of dust from gases; Apparatus for —. (P) Siemens-Schuckertwerke Ges. ..	476A
precipitation of matter from gases. (P) Strong ..	93A
precipitation; Motion of droplets and particles in field of corona discharge in —. Tolman and Karrer ..	603A
precipitation of particles from gases. (P) Morris and Haviland ..	711A
precipitation plant; Removal of dust from settling surfaces of —. (P) Pünning ..	322A
precipitation of sulphuric acid fog and of dust. Delasalle ..	720A

Ferric hydroxide; Carrying down of calcium and magnesium hydroxides by precipitates of —. Toporescu ..	503A
oxide; Carrying down of copper oxide and nickel oxide by precipitates of —. Toporescu ..	625A
oxide; Catalytic action of — on sucrose. Thomae ..	37A
oxide; Hydrons —. Weiser ..	781A
oxide; Manufacture of pure —. (P) Hemingway ..	460A
salts; Oxidation of sulphurous acid by —. Meyer ..	229A
salts; Recovery of iron from liquors containing —. (P) Frischer ..	365A
sulphate, basic; Manufacture of —. (P) McKaye, and River Smelting and Refining Co. ..	207A
Ferricyanides; Determination of —. Kolthoff ..	61A
Ferro-alloys; Determination of carbon in —. Rottmann ..	367A
Manufacture of —: ..	
(P) Sulman and Ballantine ..	160A
(P) Turner ..	601A
Ferro-aluminium; Electric smelting of bauxite for production of —. (P) Rheinische Elektrowerke A.-G. ..	754A
Ferrocenium. Hirsch ..	661A
Ferrochromium; Manufacture of —. (P) Turner ..	603A*
Manufacture of low-carbon —. (P) Sicard, and United States Ferro-Alloys Corp. ..	548A
Ferrocyanides; Determination of —. Kolthoff ..	61A
Electrometric determination of — by means of change in oxidation potential. Kelley and Bohm ..	18A
Manufacture of ammonia and formates from —. Heise and Foote ..	362A
Recovery of — from spent oxide. Grube and Dulk ..	515A
Ferromanganese as a deoxidising agent. Jung ..	411A
Manufacture of potassium permanganate from — by electrolysis. Thompson ..	106A
Reducing pyrolusite to manganous oxide before use in production of high-percentage —. (P) Hub ..	661A
Saving of — by use of fluorspar in open-hearth furnace practice. Goldmann ..	113A
Ferromolybdenum; Manufacture of — at Orillia, Ontario. Lambie ..	492A
Ferro-nickel; Manufacture of carbon-free — in a high-frequency induction furnace. Wilson ..	659A
Ferrosilicon; Electric furnace reduction of garnet with production of —. Thompson and Davenport ..	411A
Generation of hydrogen from sodium hydroxide solution and —. Weaver ..	403A
Ferrosoferrous oxide; Manufacture of — suitable for aluminothermic use. (P) Bredig and others ..	191A
Ferrotungsten; Determination of tungsten in —. Löwy ..	158A
Ferrous compounds; Catalytic action of copper salts on oxidation of — by air. Maquenne and Demoussy ..	669A
perchlorate; Manufacture of pure, stable, technical —. (P) Merck ..	267A
salts; Antitoxic properties of copper with respect to action of — on plants. Maquenne and Demoussy ..	606A
sulphide as indicator in acidimetry. Houben ..	85A
zymophosphate. Schweizer ..	672A
Fertiliser industry in Canada ..	319R
industry in Japan ..	202R
New phosphate ..	275R
Use of molasses as —. De Sornay ..	420A
Fertilisers; Artificial nitrogenous —. Russell ..	5R
containing dicalcium phosphate; Manufacture of —. (P) Sadtler ..	201A
containing nitrogen and phosphoric acid. (P) Norsk Hydro-Elektrisk Kvaestofaktieselskab ..	344A
containing phosphoric acid and alkali nitrates; Manufacture of —. (P) Reinau ..	579A
Determination of nitrate-nitrogen and nitrates in —. Moore ..	579A
Effect of various — on crop production. Jordan and Churchbill ..	242A
Exportation of — ..	186R
Furnace for manufacture of germ-free — from faeces and other organic waste products. (P) Stettiner Chamotte-Fabr. vorm. Didier ..	495A
Gas-volumetric determination of ammoniacal, nitric, and organic nitrogen in mixed —. Baldi ..	827A
Human urine and sulphite-cellulose waste lyes as —. Bokorny ..	167A

	PAGE
Fertilisers—continued.	
Investigations on — at Rothamsted	350R
made from peat : Action of various —. Tacko ..	75A
Manufacture of — :	
(P) Bohre	759A*
(P) Buck	275A
(P) Carothers and Baker	667A
(P) Earp-Thomas	126A
(P) Fjellanger, and Norsk Hydro-Elektrisk Kvaestofaktieselskab	498A
(P) Partington and Parker	759A*
(P) Philip	75A
(P) Radmann	201A
(P) Shuey and others	523A
Manufacture of ammonium nitrate —. (P) Norsk Hydro-Elektrisk Kvaestofaktieselskab	243A
Manufacture of chemical — in Sicily	44R
Manufacture of — from city and lake waste. (P) Rice, and Chemo-Mechanical Water Improvement Co.	634A
Manufacture of compound —. (P) Reinau ..	461A
Manufacture of lime-potash —. (P) De Luce ..	579A
Manufacture of — from sewage. (P) Richards and Hutchison	827A
Manufacture of stable mixed — which can be easily distributed. (P) Dahl	201A
nitrogenous : Comparative efficiency of —. Thorne	667A
nitrogenous : Extraction of potassium compounds from rocks containing potassium, and simultaneous production of —. (P) Rossi	344A
nitrogenous : Field experiments on availability of — during 1908-1917. Lipman and Blair	553A
nitrogenous — in Germany	59R
nitrogenous : New maximum prices for — in Germany	120R
nitrogenous : Relative availability of nitrates and organic —. Blair	379A
Obtaining salt mixtures suitable for — from explosives etc. containing perchlorates. (P) Dynamit-A.-G. phosphatic : Manufacture of —. (P) James	700A 634A
prepared by treating lime with end-liquors from potash works : Composition of —. Goring	731A
Products serving as —. (P) Truffaut	634A*
Prospects of supplies of — in Germany in 1921 ..	438R
Recovery of proteins for use as — from waste liquors from treatment of hides. (P) Peck, and Dorr Co. Reinforcing, bacterising, and composting organic material for use as —. (P) Manns	633A 75A
Sewage sludges as —. Brencchley and Richards	144R, 177R
Shortage of —	223R
Supplies of —	18R, 445R
(Temporary Control of Export) Bill	224R
Transformation of synthetic ammonia into — in conjunction with production of sodium carbonate. (P) L'Air Liquide	266A
Use of potassium permanganate in determining nitrogen in — by the Kjeldahl method. Frear and others	344A
<i>See also</i> Manures.	
Fertilising with carbon dioxide : Use of blast-furnace waste gases for —. Riedel	125A
Fibre, anilina- : Utilisation of —	59R
crude- : Condenser for use in determination of — in feeding stuffs etc. Clemens	431A
material : Opening out and simultaneously drying bast —. (P) Haller	482A
plants : Treatment of —. (P) Einstein	59A
receptacles : Alkali-proof —. (P) Howlett, and Research Laboratories Co.	810A
staple- : Tensile strength of —. Kraus	329A
staple- : Treatment of —. (P) Lauffs	686A
sulphite- : Manufacture of — and recovery of sulphur dioxide. (P) Fagan and others	226A
vulcanised : Manufacture of —. (P) Clayton and others	331A*
Fibres, artificial : Manufacture of —. (P) Fuller	817A
artificial : Manufacture of — from cellulose solutions. (P) Schreiner	719A
bast : Reaction for differentiation of structure of —. Haller	512A
bast : Retting of —. Kraus	11A, 816A
broom- : Improving —. (P) Nessel-Anbau-Ges.	330A
capable of being spun : Production of a tannin-like material and — from hop bines. (P) Reis	13A
Converting short brittle — into a condition suitable for spinning. (P) Deelen	330A
<i>Fourcroya gigantea</i> — in Brazil	239R
Machines for drying or carbonising —. (P) Charlesworth	12A
Machines for treating —. (P) Dudley	228A, 361A, 401A, 542A
Machines for treating articles such as — with liquids. (P) Schmidt	226A
Manufacture of — from flax. (P) Robinson	444A
for manufacture of pasteboard suitable for saturating with tar for roofings, linings, etc. : Mechanical process for obtaining —. (P) Kron	483A*
Manufacture of — from plants. (P) Nessel-Anbau-Ges.	778A
nettle : Treatment of — for textile purposes. (P) Nessel-Anbau-Ges.	778A
Obtaining — from fibrous plants, particularly nettles. (P) Nessel-Anbau Ges.	13A
Obtaining — from hop bark. (P) Dammer	59A

	PAGE
Fibres—continued.	
Obtaining — from plants. (P) Nessel-Anbau-Ges., and Hoermann	778A
Obtaining useful — and other products from reeds. (P) Verwertung Indischer Produkte Ges.	185A
Obtaining valuable — from rushes. (P) Deutsche Typha-Verwertungs-Ges.	185A
Process for making smooth, stiff, vegetable — suitable for carding and spinning. (P) Böhm und Sohu	13A
for spinning : Mechanical treatment of ramie, flax, hemp, and like plants for production of —. (P) Govaerts and Breyndt	568A*
Substitute — and their manipulation. Rasser	11A
suitable for spinning : Production of — from rushes. (P) Deutsche Typha-Verwertungs-Ges.	226A
suitable for spinning : Treatment of broom with alkali for production of —. Kempf	263A
Tensile strength of —. Kraus	329A
textile : Digestion of woody fibres with chlorine for production of —. Waentig and Glerisch	817A
textile : Influence of atmospheric exposure on —. Turner	512A
textile : Manufacture of —	
land (P) Verein der Spiritus-Fabrikanten in Deutschland	360A
(P) Wilke and Schorsch	226A
textile : Manufacture of fine — from mulberry bark. (P) Mark	360A
textile : Manufacture of — from broom. (P) Hammer	744A
textile : Manufacture of — from hop bines. (P) Küchenmeister	482A
textile : Manufacture of — from lupin stems. (P) Hoffmanns Stärkefabr. A.-G.	102A
textile : Manufacture of — from <i>Malva crispa</i> and <i>Lavatera trimestris</i> . (P) Hammer	360A
textile : Manufacture of — from raw plants. (P) Nesselanbau Ges.	400A
textile : Manufacture of — from straw. (P) Strauss	744A
textile : Manufacture of — from straw, grasses, etc. (P) Wolf and Trommer	103A
textile : Manufacture of — from straw and similar stem and bast fibres. (P) Geraer Jute-Spinnerei und Weberei A.-G.	330A
textile : Manufacture of — from typha seeds. (P) Jata-Werk für pflanzliche Füllstoffe Ges.	360A
textile : Manufacture of — from wood :	
(P) Euge	444A
(P) Mutter	102A
textile : Manufacture of resinous substances of vegetable origin suitable for impregnating substitutes for —. (P) Fuchs	241A
textile : Moistening or conditioning —. (P) Smethurst	61A*
textile : Obtaining — from bark of trees. (P) Kniebel	59A
textile : Obtaining — from woody vegetable substances, such as nettle stalks, barks, etc. (P) Hammer	444A
Treating fibrous plants, e.g., yucca, for recovery of —. (P) Loehr	292A
Treatment of —. (P) Pickup and Wilson	653A
Utilisation of — in Rhodesia	290R
Utilising willow or poplar bark for production of —. (P) Kersting	59A
vegetable : Analysis of mixtures of wool and —. Kraus and Blitz	512A
vegetable : Economy of cellulose and caustic soda in isolation, purification, and bowking of —. Freiburger	101A
vegetable : Elimination of nitrogen from — in the bleaching process. Higgins	16A
vegetable : Manufacture of —. (P) Korselt	482A
vegetable : Obtaining — for textile purposes. (P) Deutsche Faserstoff-Ges. Fulda	778A
vegetable : Process for making — lustrous. (P) Kraus and Röhm	292A
vegetable : Scouring — to accelerate and facilitate subsequent bleaching. (P) Watremez	568A, 686A
vegetable : Treatment of —. (P) Gillet et Fils, and Schwartz	513A, 541A, 542A, 654A
Fibrin : Hydrolysis of — in presence of aldehydes. Hoim and Gortner	346A
Fibrous cleaning or polishing material. (P) Reis and Co. ..	15A
material : Apparatus for scouring, dyeing, or otherwise treating with liquor —. (P) Walker	720A*
material : Manufacture of — for making paper, papier-maché, and the like. (P) Skinner	227A
material : Manufacture of textile —. (P) Hoisté	541A, 595A*
material : Obtaining — from <i>Typhaceæ</i> . (P) Hoering	568A
material from pea-pods. (P) Pöhler	185A
material for surgical dressings. (P) Von Kapff	513A
material : Treatment of vegetable —. (P) McDaniel and Kimbell	653A
materials : Colouring — :	
(P) Dennison, and American Rubber Co.	362A
(P) Gibbons, and American Rubber Co.	362A
materials : Drying and carbonising machine for —. (P) Allsop and others	185A
materials : Machines for dyeing, scouring, and washing —. (P) Whitaker and Whitaker	484A
materials : Treatment of vegetable — and production of detergents. (P) Amber Size and Chemical Co., and Weygang	59A

electric; Manufacture of artificial abrasives in —.		for heat treatment of metal articles in an atmosphere	
Brockbank	41T	of coal gas. (P) Yates and others	493A*
electric; Manufacture of iron in —. (P) Stock ..	456A	for heat treatment of metal bars etc. (P) Fuller and	
electric; Manufacture of manganese and its alloys		Bedford	416A*
in —. (P) Lenoir	118A*	for heat treatment of metallic or other bodies. (P)	
electric; Means actuated by alternating electric current		Atkinson, and Stein and Atkinson, Ltd. ..	576A*
for controlling or operating — or other		for heat treatment of metals:	
mechanisms. (P) Reid, and International Nitrogen		(P) Brighton and Peakman	302A
Co.	755A	(P) Cunningham, and Stein and Atkinson, Ltd.	339A*
Electric melting —. (P) Harvey	457A	(P) Gaunt and others	696A*
Electric — for melting non-ferrous metals and their		for heat treatment of steel, iron, or the like. (P) August	
alloys. Collins	115A	Heating —:	
Electric — for melting and refining steel. (P) Fabbr.		(P) Buell, and Tate-Jones and Co.	563A
Ital. Automobili Torino	693A	(P) Buell and others	563A
Electric metallurgical —:		(P) Gray and others	1A
(P) Electro-Metals, Ltd., and Robertson ..	787A	(P) Trioks, and Tate-Jones and Co., Inc. ..	507A
(P) Louvriér	548A	for heating liquids. (P) Wellman, and Kansas City	
(P) Moore	70A*	Gasoline Co.	440A
Electric — for metals, ores, etc. (P) Morgan Crucible		for heating metal articles. (P) Aktiebolaget Svenska	
Co., and Speirs	575A	Kullagerfabriken	493A*
electric; Method of operating —. (P) Trembour,		for heating metal articles and the like. (P) Southorne	
and Ludlum Electric Furnace Corp.	494A	for heating metal blooms; Slide tracks for —. (P)	
Electric — and method of operation. (P) Groeger ..	375A	Mathy	271A*
electric; Method of oxidising materials, e.g., steel billets,		for heating metals. (P) Williams and Ahlen	413A
in —. (P) Mayer and Kennedy	726A	for heating steel ingots. (P) Koller	29A
electric; Mounting of electrode arms in tilting —.		Improvements in technique of firing of —, with special	
(P) Moore	494A*	reference to open-hearth furnaces. Tafel	26A
electric muffle; Doors for tilting —. (P) Imbery ..	340A*	and iron alloy lining therefor. (P) Copland, and Elyria	
electric; Problems in smelting in —. Holmgren ..	237A	Iron and Steel Co.	507A
electric; Raising and lowering electrodes of tilting —.		Lids for melting —. (P) A.-G. Brown, Boveri, & Co.	339A*, 549A*
(P) Moore	494A*	or the like; Burners for firing —. (P) Atkins and	
electric; Recent developments of — in Great Britain.		Colquhoun	509A*
Campbell	224T, 250R	or the like; Device for emptying the contents of bins	
Electric — for reducing oxidised zinc concentrates by		into —. (P) Sulzer Frères	356A*
carbon. (P) Thomson	29A	for manufacture of aluminum nitride. (P) Hermao ..	570A
electric; Regulator system for —. (P) Bouton, and		for manufacture of germ-free fertiliser from faeces and	
Westinghouse Electric and Manufacturing Co. ..	631A*	other organic waste products. (P) Stettiner	
Electric resistance —. (P) Simon and Sarron ..	340A*	Chamotte-Fabr. vorm. Didier	498A
Electric resistance — for treatment of zinc ores.		Martin; Heating — with cold coke-oven gas.	
Fulton	193A, 194A	Springorum	299A
electric; Rotary — for continuously melting zinc dnt.		Martin; Operation of tilting — using a mixture of	
(P) Cornelius	725A	low-grade and high-grade gas. (P) Deutsch-	
Electric rotary muffle —. (P) August	696A	Luxemburgische Bergwerks- u. Hütten-A.-G., and	
Electric smelting —. (P) Hole	548A	Klinkenberg	69A
Electric — for smelting iron ores (P) Shipton ..	492A	Martin; Substituting coke or the like for pig iron in	
electric smelting; Manufacture of electrodes of —.		operating —. (P) Thyssen and Co., and Thomas	
(P) Olsen	269A	Means for consuming smoke in —. (P) Halt	356A*
Electric steel hardening —. (P) Wild and Barfield ..	724A	Means for facilitating repair of metallurgical and like—	
electric; Step induction regulator for —. Short ..	373A	(P) Hardy	416A*

Furnaces—continued.	PAGE
Mechanical. (P) Ramén	740A*
for melting glass and other purposes (P) Shaw and others	573A
for melting metals. (P) Harvey	117A
for melting and refining metals. (P) Cohen and Catterall	694A
Metalsmelting —. (P) Sinclair	413A
Metallurgical —. (P) Griffiths	694A
(P) Howell	457A, 603A*
metallurgical; Heat regenerator for —. (P) Skluner	661A
metallurgical; Heating — with heavy oil. Gonvy	299A
metallurgical; Lining of —. (P) Ely	162A*
metallurgical; Port construction for —. (P) Downs, and Miller, jun.	548A
Metallurgical tilting —. (P) Aubert	725A*
Method of charging reverberatory —. (P) Charles	725A
Method of heating —. (P) Renner	321A
Muffle —. (P) Amsler	507A
(P) Hutchins	145A*
(P) Zetsche	1A
muffle; Method of heating —. (P) Zieren	437A
Muffle and semi-muffle and like —. (P) Priest	619A
for nitrogen fixation: (P) Crowell, jun., and Nitrogen Products Co.	21A
(P) Hidden, and Nitrogen Products Co.	657A
for oil-cracking stills. (P) Wellman, and Kansas City Gasoline Co.	221A
oil-fired; Burners for —. (P) Woolley	774A*
Oil-fired — for melting glass and other fusible substances. (P) Moha	491A*
Oil-fuel burners for —. (P) Simpson and Sons (Bolts and Nuts), and Everton	145A*
Open-hearth —. (P) Carter and McLain	302A, 603A*
(P) Cromwell and Mehthora	457A
(P) Griggs	304A*, 725A*
(P) McKune	493A
(P) Waring and Waring	413A
open-hearth steel; Heating basic — with a mixture of producer gas and coke-oven gas. Schneider	410A
Operation of —. (P) Slegward and others	809A
Pot —. (P) Knoedler, and Welsbach Co.	647A
Producer-gas —. (P) Bildt	321A
for producing hot air for drying and other purposes. (P) Schlatter, Frorath, & Co.	1A
for production of mineral distillates of definite composition. (P) Fadden	413A
for production of sulphates from bisulphates. (P) Verein Chem. Fabr. in Mannheim	783A
Pyrites —. (P) Bracq	365A*
Recovery of combustible material contained in ashes from industrial —. (P) André	715A
Recuporative —. (P) Smallwood	739A, 739A*
Recuporative — of new type. Rosenhain and Coad-Pryor	213A
Recuperators or regenerators for —. (P) Chaptaine	564A*
Refuse destructor —. (P) Brechot	278A
Regenerative —. (P) Hurex	327A*
Regenerative soaking-pit —. (P) Steia, and Stein et Cie.	662A*
Retort — for recovery of zinc by reduction of zinc oxide. (P) Bursitzky	69A
Reverberatory — for melting metals and alloys. (P) Wüst	270A
Reverberatory — for smelting steel and other metals of high melting point. (P) Schmid	269A
Reverberatory — for use with liquid fuel. (P) Strub	563A
Reversible gas-heated —. (P) Reasonson	214A
Ring —. (P) Broadwell, and Aluminium Co. of America	256A
(P) Doerschuk, and Aluminium Co. of America	256A
Roasting —. (P) Alinder, and Allis-Chalmers Manufacturing Co.	302A
(P) Fouarge	373A*
for roasting blende, pyrites, or other minerals: Rotary —. (P) Biogham, and Huntington, Heberlein, and Co.	31A*
for roasting electrodes and pulverulent materials in crucibles or moulds. (P) Meiser	576A
roasting; Gas-fired —. (P) Donnersmarchhütte	457A, 575A
Oberschlesische Eisen- und Kohlewerke A.-G.	823A*
for roasting ores; Mechanical —. (P) Huntington, Heberlein, and Co., and Bingham	270A
Roasting — for sulphurous ores. (P) Soc. Anon. de Védria, and Marcotty	270A
rotary; Composite lining for —. (P) Rockwell, and Rockwell Co.	321A
rotary; Driving mechanism for —. (P) Summers and Whitlard	538A*
Rotary grates for —. (P) Tréfois	814A*
Rotary muffle —. (P) August	590A
rotary; Sectional lining for —. (P) Rockwell, and Rockwell Co.	256A
rotary; Treatment of lime mud in —. (P) Polysius	22A
Selection of refractories for industrial —. Rochow	111A
shaft; Blast-proof clog of discharging devices for —. (P) Stehmann	774A*
Shaft — for burning lime, dolomite, etc., with built-in gas producers. (P) Skuballa	256A

Furnaces—continued.	PAGE
Shaft — for burning powdered limestone. (P) Müller	821A
Shaft — and gas producers. (P) Chaudière	179A
Shaft — for synthetic production of high-grade foundry and pig-iron. (P) Rombacher Hüttenwerk, and others	68A
shaft; Utilisation of waste heat from —. (P) A.-G. für Zinkind. vorm. Grillo	809A
Siemens-Martin — with built-in gas producer. (P) Ostendorf	29A
Smelting —. (P) Gannt and Brookfield	576A*
(P) Jones, and U.S. Smelting Furnace Co.	373A
(P) Ward, and Independent Mines Smelting Co.	631A
(P) Ward and others	691A
Smelting — heated by oil or gas. (P) Schmidt	823A
smelting; Open-side water-jacket for —. (P) Carstens, and American Metal Co.	302A
smelting; Regenerators for —. (P) Kühn	602A
for steam boilers, kilns, and the like. (P) Nash	256A
Steel-making and like —. (P) Wellman, Seaver, and Head, Ltd., and Gray	161A
Steel smelting —. (P) Fuller, and Fuller Engineering Co.	238A
Tilting crucible or melting pot —. (P) Soc. des Allages et Brozes Forgeable	338A, 413A
for tinning and like operations. (P) Harper, Sons, and Bean, Ltd., and Conroy	631A*
Tunnel —. (P) Bigot	590A
Tunnel — for electrodes and similar materials. (P) Meiser	755A
tunnel muffle; Heating of —. (P) Schürter	821A
Water-cooled inlets of ore reducing and refining —. (P) Charles	631A*
Furs; Electrical process and apparatus for dyeing —. (P) Bloom	484A
Fusain and coal dust. Sinnatt and others	438A
Fused products; Apparatus for obtaining material in a state of division from —. (P) Minton, and United Alkali Co.	448A
Fusel oil; Composition of —. Luce	636A
Fustic; Differentiation of extract of old — and quercitron extract. Justia-Mueller	816A

for table ware; Comparative effects of soda and potash on lead —. Hodkin and Turner ..	546A
for table working. Travers ..	407A
tank furnaces; Preliminary firing of —. Fisher ..	192A
Thermal dilatation of — at high temperatures. Peters and Cragoe ..	572A
trade of Hongkong ..	311R
tubes; Manufacture of reinforced —. (P) Küppers ..	450A*
tubing; Discoloration produced by lead, antimony, and arsenic in lampworked —. Hodkin and Turner ..	627A
ware; Factory inspection of —. Turner ..	53R
ware; Importation of — ..	419R
ware; Investigations on chemical —. Muirhead and Turner ..	192A
ware; Proposals for standardisation of chemical —. Thiene ..	192A
ware; Testing of volumetric — at the National Physical Laboratory ..	76R
works furnaces; Recent improvements in designs of gas producers and —. Atkinson ..	192A
-works; Specifications for refractories for use in —. Rees ..	233A
Glasses; Annealing temperatures of magnesia-soda —. English and Turner ..	407A
containing magnesia; Thermal expansion of —. English and Turner ..	546A
Density of soda-lime —. English and Turner ..	546A
Density of soda-magnesia —. English and Turner ..	627A
Durability of lime-soda —. Cauwood and others ..	407A
Heat expansion of soda-lime —. English and Turner ..	407A
Influence of lime on value of Young's modulus of elasticity for lime-soda —. Clarke and Turner ..	407A
Magnesia-soda —. Davidson and others ..	407A
Optical properties of some lime-soda —. Clarke and Turner ..	546A
Properties of lime-soda —. Davidson and Turner ..	407A
Glauber's salt. See Sodium sulphate.	
Glaucinite; Extraction of potassium compounds from —. (P) Hart ..	63A
Glazed ware; Kilns for burning —. (P) Webster ..	490A
Glazes; Development of terra-cotta —. Hill ..	366A
Devitrification phenomena in — and their prevention. Berg ..	296A
Study of — involving some colours produced by nickel oxide. Whitmer ..	628A
Substitutes for tin oxide in —. Minton ..	366A
Transparent — for ivory and white pottery ware. Heinsteins ..	296A
Glazing cement for fireclay retorts and furnaces. (P) McMin ..	192A
Gleditschia triacanthos seeds; Oil from and enzymic properties of —. Kryz ..	240A
Gliadins of rye and wheat; Colloid chemistry of — with special attention to gluten and baking problems. Lüers ..	499A
Globulin of coconut. Johns and others ..	169A
of jack-bean. Sumner ..	169A
Glucinum; Separation of iron, aluminium, chromium, titanium, zirconium, and — by means of sodium carbonate. Wenger and Wuhmann ..	46A

	PAGE		PAGE
Gluconic acid; Preparation of — from dextrose. Herzfeld and Lenart	205A	Glycol; Compound of phosphoric acid and —. Fischer and Pfähler	790A
Glucosan. Pletet and Castan	607A	Determination of —. Müller	642A
Glucose; Manufacture of — in Transvaal	271R	Manufacture of — from ethylene. (P) Chem. Fabr. Grishelm-Elektron	385A
production in Canada in 1918	386R	Glycols; Preparation of ethylene- and propylene- — from oil-gas. Brooks	384A
See also Dextrose.		Glyoxal; Manufacture of —:	
Glucoside hydrolysed by emulsin; Scabiosin, a new —. Bourquelot and Bridel	312A	(P) Rosshard	426A
Glucosides. Karrer and Weidmann	348A	(P) Wohl and Bräunig	765A
Configuration of —. Karrer	348A	Preparation of — by action of ozone on acetylene. Wohl and Bräunig	279A
Constitution of amygdalin. Karrer and others	800A	Glyoxaline nucleus; Some properties of and dyestuffs containing the —. Pyman	480A
Distillation of certain — under diminished pressure. Pletet and Goudet	40A	Gold alloy; Manufacture of a white —. (P) Belas 270A. 416A*	
Extraction of — from two indigenous orchids and their identification with ioroglossin. Delauney	672A	-copper alloys; Hardness and resiliency of —. Portevin and Durand	412A
β -Glucosidoreosaccharic acid methyl ether; Synthesis of —. Karrer and Weidmann	348A	Electro-deposition of — from cyanide solutions. Christy	337A
Glue; Determination of jellyfying power of — by means of the polariscope. Smith	731A	foil; Production of transparent and opaque enamels on wrought iron (sheet iron) by means of layers of —. (P) Fix and Schmidt	491A
Determination of the tensile strength of —. Hopp	378A	Growth phenomena of —. Bentell	269A
Jellies; Testing the strength of —. Low	378A	Microchemical detection of —:	
Jelly strength of —. Sheppard and others	758A	Bayer	721A
making; Influence of method of manufacture on use of casein in —. Buttermann	274A	Emich	721A
Manufacture of bone or hide — which remains liquid in the cold. (P) Luftfahrzeugbau Schütte-Lanz	827A	New methods in hydrometallurgy of —. Freeman	9R
Manufacture of feeding-stuff, fat, and — from bones. (P) Goslar	733A	ore; An unusual process in treatment of —. Gardiner	299A
manufacture in New South Wales	445R	output of Transvaal	218R
Manufacture of — in the tropics from tannery refuse. Srinivasan	123A	production in Federated Malay States	154R
Manufacture of water-resistant —. (P) Grünwald	497A	production in Germany; Possibility of —.	238R
Properties and constitution of —. Bogue	605A	Production of radium and — by decomposition of mercury. (P) Perez	455A
solutions; Apparatus for concentration of —. (P) Goslar-Apparatenbau Samstag und Co.	758A	Recovery of —. (P) Thayer	118A
substitute; Manufacture of —. (P) Bayer und Co.	578A	-silicon alloys. Di Capua	370A
Glutamic acid and its salts; Decomposition of — on heating. Skola	673A	-silver alloys; Action of <i>aqua regia</i> on — in presence of ammonium salts. Pollard	299A
Gluten; Colloid chemistry of rye and wheat gliadins, with special attention to —. Lüers	499A	soils; Coagulation of —. Westgren	117A
Determination of dry — in flour. Bouyer	204A	Gold Coast Colony; Trade of — in 1918	320R
Determination of wet — in low-grade flours. Bouyer	276A	Gold Coast Northern Territories; Trade of — in 1918	99R
Manufacture of a colloidal solution, neutral to the taste, from —. (P) N. V. Jurgens Vereenigde Fabr.	204A	Government laboratory. See under Laboratory.	
Separating starch from —. (P) Conte	461A	orders and notices; Various —. 19R, 41R, 61R, 82R, 117R, 137R, 152R, 172R, 190R, 206R, 240R, 262R, 309R, 330R, 364R, 387R, 404R. 420R.	
Glutin; Benzene derivatives in —. Salkowski	698A	Grading apparatus for minerals and the like. (P) Richardson	576A*
Glycerides; Function of catalyst in addition of hydrogen to unsaturated —. Thomas	12T	crushed rock and other materials; Separators for —. (P) Sturtevant	477A*
Mechanism of addition of hydrogen to unsaturated glycerides in presence of finely divided nickel. Thomas	10T, 10R	of finely-divided material; Electrical —. (P) Schmidt, and International Precipitation Co.	393A
Synthesis of α -mono- —. Fischer and others	790A	ores or the like. (P) Gasche	457A*
α -Glycerides; Application of acetoneglycerol to preparation of pure —. Fischer and Pfähler	790A	Grain; Converting — into paste or dough. (P) Pointe	525A
Glycerin; Determination of trimethyleneglycol in distilled dyanomite — and in first runnings. Rohahn	314A	Disintegrating and extracting liquid from —. (P) Melzer	565A
Exports of — from U.S.A.	312R	Steeping and malting —. (P) Rummel	524A
Manufacture of —. Verbeek	790A	Granulating pasty or semi-fluid materials; Apparatus for finely dividing or —. (P) MacLachlan	39A
Obtaining pure — from liquids containing it. (P) Bayer und Co.	121A, 121A	Grape must; Determination of minute quantities of iron in —. Mathieu	431A
Obtaining — from soap lyes. (P) Blum and Francke	306A	seed; Possibility of commercial utilisation of —. Shrader	131A
solutions; Obtaining concentrated — from dilute, highly impure solutions. (P) Löfl	240A	Graphite in 1918	78R
Splitting fats and oils for manufacture of fatty acids and —. (P) Twitchell Process Co.	697A*	articles; Manufacture of —. (P) Linbarger, and Carborundum Co.	450A
substitute; Phthalic acid ester salts as —. (P) Rössler	44A	ash and bond clays; Fusibility of mixtures of —. Long	628A
substitutes; Alkali lactates as —. Neuberg and Reinthur	801A	Deflocculating —. (P) Acheson	564A
substitutes from lactates. (P) Chem. Fabr. Goldenberg, Geromont, und Co.	756A	electrodes, specially suitable for searchlights. (P) Conrad	261A
U.S. foreign trade in —	22R	Enclosing pieces of — in refractory metals. (P) Ising and Borofski	303A
Glycerol; Bacterial decomposition of — in wine. Müller-Thurgau and Osterwalder	345A	industry of Canada. Spence	356R
Correlative formation of acetaldehyde and — by action of sugar. Neuberg and Reinthur	76A	Manufacture of flake — from kish. (P) Osgood and Kenner	233A
formation in alcoholic fermentation; Natural and artificial —. Neuberg and Reinthur	168A	Moulding —. (P) Allen	451A*
Influence of presence of trimethyleneglycol on estimation of fermentation —. Rohahn	77A	obtained from cast iron; Crystalline nature of —. Iokibe	785A
Manufacture of pure — from liquids containing it or from crude glycerin. (P) Elektro-Osmose A.-G.	756A	plate heated electrically to a high temperature; Luminous phenomena observed in neighbourhood of —. Hemsalech	31A
Manufacture of — from sugar. (P) Ver. Chem. Werke A.-G.	608A, 670A	production in German Austria	133R
Mechanism of "fixation" method of decomposition of sugar into acetaldehyde and —. Neuberg and Hirsch	38A	Purification of natural —. (P) Ridoni, and Soc. Talco e Grafiti Val Chisone	23A
In wines. Mathieu	669A	situation in Ceylon	43R
Glycerol β -monochlorhydrin. Smith	674A	situation in Madagascar	83R
Glycerophosphatase of seeds. Nemece	244A	in Western Australia	236R
Glycerophosphate solutions; Conversion of — into a crystalline preparation. (P) Bergell	802A	Graphitic acid — a colloidal oxide of carbon. Hulett and Nelson	487A
Glycerophosphates; Detection of inorganic phosphate in —. Litzius	266R, 610A	Determination of —. Selvig and Ratliff	486A
Glycerophosphoric acid in kephalin. Levene and Rolf	133A	Graphitic carbon. See under Carbon.	
Glycine; Manufacture of complex silver salts of —. (P) Napp	640A	Graphitising carbon electrodes. (P) Szarvasy	824A
Glycoen; Colorimetric determination of —. Thieulin	278A	Grass; Extraction of shave — with dry and moist benzene under pressure. Fischer and Kleinstück	218A
		Manufacture of textile fibres from —. (P) Wolf and Trommer	103A
		Production of paraffin, waxes, oils, or fats from —. (P) Von Porat	7A
		Grass trees; Extraction of gum-resin from —. (P) Pooley and Stevens	697A
		Grasselli medal; Presentation of — to Dr. A. Rogers	374R

Linolin; Manufacture of — (P) Broadgate and Harmon	728A
Separation of — from crude wool-grease and the like. (P) Metzger	272A
Lard; Fat-soluble growth-promoting substance in — Daniels and Longhlin	609A
Latex. See under Rubber.	
Launders' Research Association; British —	41R
Laundry preparations; Efficiency of active oxygen in — Grün and Jungmann	16A
<i>Lavatera trimestris</i> ; Manufacture of textile fibres from — (P) Hammer	360A
Lawsonia; Constitution of — Tommasi	594A
<i>Lawsonia inermis</i> ; Constitution of colouring matter of — Tommasi	594A
Leaching machines. (P) Dyer	740A
materials. (P) Steen	394A
tank. (P) Giesecke, and Ray Bros. Corp.	257A
Lead accumulator; Reactions of the — MacInnes and others	416A
Action of water on — Liverseege and Knapp	9R, 27R
Alloy to serve as substitute for antimony in hard — (P) Zimmer	161A
alloy for use as supports for active material in lead accumulators; Hard — (P) Accumulatoren-Fabr. A.-G.	576A
or its alloys; Coating metallic surfaces with — (P) Berlin-Burger Eisenwerk A.-G.	303A
alloys; Manufacture of — (P) Arend	68A

Lead—continued.	PAGE
Anodic corrosion of — in sodium hydroxide solutions. Brown and others	603A
antimony alloys; Determination of antimony in —. Bertaux	603A
Attempt to determine if common — could be separated into isotopes by centrifuging in the liquid state. Joly and Poole	269A
bismuth alloys. Herold	723A
Chemical sheet —. Jones	221R, 250R, 255R
coated iron. Baskerville	268A
Coating metals with —. (P) Montag and Laube	303A
coatings on metals; Production of —. (P) Berlin-Burger Eisenwerk A.-G.	162A
copper smelting process. (P) Johnson	339A
copper-zinc ores; Treatment of complex —. Hommel	160A
Determination of — in acid solution. Evers	266R, 612A
Determination of small quantities of — in ores etc. Hastings	837A
Dezincing —. (P) Harris	456A
Extraction of — from its ores. (P) Elmore	662A*
Extraction of zinc and — from ores. (P) Elmore	603A*
hard; Substitute for —. (P) Hanemann and Stockmeyer	161A
(P) Stockmeyer and Hanemann	161A, 376A
Hardening effects of various elements upon —. Thiele	454A
Industry in Japan	289R
Influence of — on catalytic activity of platinum. Mast	377R
and like ores and products; Smelting —. (P) Cavers, and Garred-Cavers Corp.	549A
Manufacture of —. (P) Greenwood	456A
Manufacture of alloys of copper, zinc, and —. (P) Vereinigte Hüttenwerke Burbach-Eich-Düdelingen A.-G.	161A
Manufacture of alloys of copper, zinc, tin, and —. (P) Vereinigte Hüttenwerke Burbach-Eich-Düdelingen A.-G.	161A
Occurrence of — in South Africa	184R
ores; Extraction of molybdenum compounds from yellow —. (P) Deutsche Molybdaen-Werke	724A, 823A
plating from sodium hydroxide lead baths by use of addition agents. Mathers	603A
processes; Bill for regulation of employment of women and young persons in —.	384R, 440R
Rapid estimation of — in cassia oil. Lubatti	35T
Recovery of silver and — from sulphide ores and metallurgical products. (P) Amalgamated Zinc (De Bavy's), Ltd., and Gancin	117A
Recovery of — from solutions. (P) Rumbold	68A
Refining of —. (P) Harris	456A
(P) Leathart, and Locke, Blackett, and Co., Ltd. refining slags and residues; Complete analysis of —. Stahl	372A, 600A
Removing — from copper scrap. (P) Jones, and Westinghouse Electric and Manufacturing Co.	661A
Separation and determination of bismuth and —. Luff	283A
smelting; Production of slags rich in iron from —. (P) Buddus	69A
sodium alloys. (P) Stockmeyer and Hanemann	303A
sodium-mercury alloys. Goebel	116A
sodium-tin alloys. Goebel	116A
Solubility in the solid state of tin in —. Parravano and Scorteci	412A
sulphur-oxygen; Equilibria in the system —. Physical chemistry of roasting. Reinders	338A
tungsten alloys; Manufacture of —. (P) Falkenberg	30A
Use of — as substitute for platinum. Hutter	175A
zinc-copper alloys; Manufacture of —. (P) Arend	117A
and zinc deposits of Gaspe. Beidleman	70R
zinc ores; Treatment of complex —. Hommel	160A
zirconium alloys; Manufacture of —. (P) Petinot, and U.S. Ferro-Alloys Corp.	415A
Lead arsenate; Manufacture of —. (P) Barstow, and Dow Chemical Co.	689A
(P) Butler, and Harshaw, Fuller, and Goodwin Co.	109A
(P) Hedenburg and others	571A
arsenate; Preparation containing —. (P) Goodwin, and Lathier Chemical Co.	40A
borates. Thompson	230A
chloride; Vapour pressure of —. Eastman and Duschak	294A
chromate; Iodometric determination of chromic acid in —. Gröger	34A
chromates; Use of — in the ceramic industry. Bock	341A
Gröger	332A
compounds; Use of — in the ceramic industry. Petrik	722A
cyanide. Gupta	332A
dioxide; Colorimetric determination of — in litharge. Morgan	107A
hydride. Paneth and Nöring	747A
oxides; Determination of volatile matter in —. Andersen	19A
peroxide; Manufacture of electrodes composed of manganese peroxide or/and —. (P) Bardt	824A
peroxide; Reguline —. Palmær	107A
pigments; Manufacture of —. (P) Seeley	164A
plaster; Analysis of —. Wilkie and Wain	71R
salts; Manufacture of —. (P) Sperry	545A*

Lead—continued.	PAGE
silicate melts; Volatilisation of lead oxide from —. Anderson	21A
sulphate; Problem of reducing —. Flynn	301A
White —. See under White lead.	
Leather, artificial; Manufacture of —. (P) Somerville, and New York Belting and Packing Co.	407A
artificial; Manufacture of — and of similar products. (P) Reidel	407A
chamois; Manufacture of substitute for —. (P) Röhru	827A
charcoal. See under Charcoal.	
chrome; Detanning —. (P) Immendorfer	460A
(P) Lamb	497A*
chrome; Problems for research laboratories in connexion with —. White	406A
chrome; Utilising waste —. (P) Bennert	74A
Detection of sugar in —. Grasser	418A
Determination and behaviour of free sulphuric acid in —. Immerhiser	731A
Determination of hide substance in —. Chambard	605A
Drying varnished (patent) —. (P) Schulz and Heyl	731A*
industry; Progress in — in 1919. Thompson	33R
industry; Projected research institute for — in Saxony	238R
industry in South Africa	94R, 219R
-like masses; Manufacture of — from yeast and formaldehyde. (P) Blücher and Krause	242A
for linings, especially from inferior portions of hides; Increasing the durability of —. (P) Hoffmeister and Paessler	793A
Manufacture of —. (P) Blatz and Blatz	243A
(P) Rogers	606A
Manufacture of glazed kid —. (P) Zdanowski	606A
Manufacture of tough and durable iron-tanned —. (P) Menzing	124A, 199A
(P) Stecher and others	553A
Manufacture of waterproof, vegetable-tanned —. (P) Rechberg	460A
Manufacture of waterproof wear-resisting —. (P) Rechberg	419A
mocha; Manufacture of —. (P) Forse and others	497A*
Rapid determination of nitrogen in —. Enna	730A
Rendering — resistant to chlorine. (P) Askenasy	460A
Research Institute in Germany; New — scrap; Manufacture of food or fodder from —. (P) Bader	78A
Seasoning —. (P) Zdanowski	696A
Sources of error in Kjeldahl determination of nitrogen in — and modified method of expelling the ammonia. Kahn	731A
substitute; Composition for use as — and for similar purposes. (P) Christenson, and Johns-Manville Co.	343A
substitute; Manufacture of sole- —. (P) Von Heynitz	633A
substitutes: (P) Drury	166A
(P) Matthaei, and Armstrong Cork Co.	166A
(P) Miller	419A*
(P) Waller	343A
substitutes; Grinding machines for sawdust to be used for —. (P) Marshall	35A
treated with cellulose derivatives. (P) Byers, and Products Syndicate	242A
Treatment of —. (P) Hawkins	166A
Treatment and utilisation of scrap and waste —. (P) Laasdown and Magnus	36A
Treatment of varnished (patent) —. (P) Schulz and Heyl	166A
waste; Manufacture of hard flooring or insulating slabs from —. (P) Gronrose	26A
Leaves; Extraction of foliage — with dry and moist benzene under pressure. Fischer and Kleinstück	218A
Lecithin; Purification of —. (P) Hildebrandt	313A
Recovery of — from animal and vegetable substances. (P) Baumann and Grossfeld	582A
Legal intelligence:	
Aluminium welding patents; Alleged infringement of —	206R
Caustic soda contract	42R
Charter; Alleged infringement of —	361R, 383R

Payman	95A	analysis; Application of Ackerman's refraction method to —. Langkammerer	39A
Uniform movement of flame in mixtures of nitrogen, oxygen, and —. Payman	181A	Apparatus for atomising and drying —. (P) Chem. Verwertungsges.	581A
Methyl acetate; Conversion of methyl chloride into —. Whiston	384A	Apparatus for granulating or finely dividing —. (P) MacLachlan	39A
Methylal; Interaction of — with unsaturated cyclic hydrocarbons. Radcliffe	259A	artificial; Manufacture of —. (P) Erslev	382A*
Methyl alcohol; Conversion of methyl chloride into —. Whiston	384A	Carbon dioxide content of — as a basis for distinguishing heated from unheated milk. Van Slyke and Keeler	499A
Critical study of methods for detection of —. Gettler	613A	Carbonic acid and carbonates in cow's —. Van Slyke and Baker	130A
Dangers of consumption of —. Hunt	38R	Composition of sediment obtained in Gerber's butyrometer in determination of fat in —. Reiss and Diesselhorst	39A
Detection of — by formation of methyl <i>p</i> -bromobenzoate. Antenrieth	585A	Conditions causing variation in reaction of freshly drawn —. Van Slyke and Baker	130A
Detection of — in spirits. Hassé	345A	containers	131R
Determination of —:		Decomposition of hydrogen peroxide by micro-organisms extracted from pasteurised —. Fouassier	204A
Heiduschka and Wolf	558A	Dehydration of —. Wright	128R
Schryver and Wood	73R, 466A	Desiccating —. (P) Stutzke, and Buhl Co.	702A
Differentiation of ethyl alcohol and —:		Destruction of bacteria in — by electricity. Beattie and Lewis	292R
Pannwitz	38A	Detection of abnormal — based on hydrogen ion concentration. Baker and Van Slyke	130A
Sabalitschka	245A	Detection of added water in — by means of the refractometer. Utz	608A
fermentation; So-called —. Von Lippmann	732A	Detection of hydrogen peroxide in pasteurised — by means of gualacum tincture. Fouassier	204A
Manufacture of —. (P) Christiansen	350A*	Determination of added water in —. Goldan, jun.	39A
Manufacture of formaldehyde, methyl formate, acetone, and — by dry distillation of formates. (P) Hofmann	313A	Determination of fat in —. (P) Höyberg	277A, 831A*
Poisoning by	131R	Determination of keeping quality of —. Baker and Van Slyke	130A
Research in connexion with synthesis of —	379R	Determination of lactose in altered —. Hildt	169A
Methylamine; Preparation of — from ammonium methyl sulphate. Denham and Knapp	384A	Differentiation between poor and adulterated —. Hodgson	310A
Methylated spirit. See under Spirit.		dried; Freightage charges on —	223R
Methyl bromide; Preparation of — from dimethyl sulphate. Boulin and Simon	312A	Drying and thickening — by means of compressed air and heated air or gases. (P) Galland	277A
Methyl carbonates; Chlorinated —. Kilg and others ..	206A	Evaporator and pasteuriser for —. (P) Ruff	733A
Methyl chloride; Antiseptic action of —. Salkowski ..	702A	-fat; Manufacture of —. (P) Phelps and others	798A
Conversion of — into methyl alcohol and methyl acetate. Whiston	384A	Heat coagulation of —. Sommer and Hart	130A
Manufacture of mixtures of ethyl chloride and — for use as solvents for extraction purposes. (P) Henning	833A	Improvement and treatment of —. Rasch	608A
Preparation of — from dimethyl sulphate. Boulin and Simon	312A	Influence of acidity of — on velocity of inactivation of the peroxidase by heat. Bouma and Van Dam	169A
Methyl chlorosulphonate; Action of water on —. Guyot and Simon	466A	Influence of formaldehyde on analysis of —. Porcher	346A
Methyl derivatives of arylamine compounds; Manufacture of —. (P) Mailhe	511A	Influence of various carbohydrates on curdling of —. Aschenheim and Stern	556A
Methylene chloride; Antiseptic action of —. Salkowski ..	702A	Limitations of reductase test for determining quality of —. Rahn	796A
Methyl ethyl ketone; Production of — from <i>n</i>-butyl alcohol. King	134A	Manufacture of condensed and evaporated — in New Zealand	111R
Methyl formate; Manufacture of formaldehyde, methyl alcohol, acetone, and — by dry distillation of formates. (P) Hofmann	313A	Manufacture of humanised —. (P) Timpe	525A
Methyl formates; Industrial chlorinated — and their analysis. Delépine	205A	Manufacture of reconstructed —. (P) Bosworth, and Boston Floating Hospital	525A
N-Methylhexamethylenetetramine; Manufacture of salts of —. (P) Tschunke, and Chemical Foundation, Ioc.	802A*	Micro-organisms persisting in — after pasteurisation; their rôle in decomposition of hydrogen peroxide. Fouassier	637A
Methyl orange; Effect of change in temperature on colour changes of — and on accuracy of titrations. Tizard and Whiston	316A	Pasteurisation of —. Orla-Jensen	555A
as indicator. Macri	611A	powder; Manufacture of — in New Zealand	111R
Methylpelletierine. Tanret	638A	Preventing the souring of —. (P) Marcus	423A
Methyl red; Preparation of —. Desvergues	611A	Process for removing cream from —. (P) Clavel	40A, 465A*
Methyl β-tetra-acetylglucosidoanthranilate; Synthesis of —. Karrer and Weldmann	348A	product; Condensed —. (P) Diek	785A
β-Methylumbelliferone; Formation of — as a reaction of acetoacetic acid and its esters. Arriguel and Garcia	279A	products; Manufacture of artificial —. (P) N. V. Jurgens' Vereen. Fabr.	671A
Metric system; Report on compulsory adoption of — in United Kingdom	385R	records; Interpretation of —. Monier-Williams	145R
		serum obtained by spontaneous curdling. Grossfeld	556A
		serum; Preparation of — for refractometric measurements. Ambühl and Weiss	464A
		sour; Gerber's method of determining fat applied to —. Day	830A
		Sterilising and preserving —. (P) Moscrop	40A
		substitute; Manufacture of —. (P) Moses	382A
		sugar. See Lactose.	
		Sulphuric acid unsuitable for use in determination of fat in — in Gerber's butyrometer. Reiss	637A
		Treatment of —. (P) Bucl	246A
		Water-soluble vitamin in —. Osborne and Mendel	422A

	PAGE		PAGE
Millboard; Impregnating articles of — to render them waterproof. (P) Slight and Lacy	14A	Molasses,—continued.	
Manufacture of light-weight — from bark of trees. (P) Zimmermann	59A	Production and uses of —. West	380R
Mimosa bark and tanning extract; Sugars in —. Harvey	242A	Pycnometer for determining specific gravity of —. Newkirk	829A
Mineral constituents in organic substances; Determination of — especially in those containing phosphorus. Grossfeld	470A	Recovery of by-products from waste liquors from Steffen's process of desaccharifying —. (P) Bradford and Broadhead	555A
oils. See under Oils, Hydrocarbon.		Standards for differentiating between American table syrups and —. Owen	126A
output of United Kingdom in 1919	362R, 441R	Use of — as fertiliser. De Sornay	420A
Rights (Acquisition) Bill	187R	Molecule; Structure of the — in crystalline solids. Bragg	335R
royalties; Nationalisation of —	384R	Moler. See Kieselguhr.	
waters. See under Waters.		Molybdenite; Flotation of —. Oliver	412A
Minerals; Colloidal colouring substances in —. Doelter	155A	Flotation process for recovery of —. (P) Thornhill, and General Engineering Co.	788A
Development in production of — during last 25 years. Merricks	165R	ores; Occurrence, detection, and determination of molybdenite in —. Bonardi	630A
Micro-analytical determination of carbon dioxide and water in —. Alnström	176A	Molybdenum; Application of rotating zinc reductor to determination of —. Scott	530A
Miner's safety lamp. Cadman	145R	articles; Manufacture of —. (P) Reimann	30A
Mines and quarries: general report with statistics, 1918. Part II. Labour. Part III. Output	63R	-cobalt-chromium alloys; Analysis of —. Camp and Marden	753A
and quarries. General report with statistics, 1919. Part II. Labour. Part III. Output	441R	Colour reactions of —. Barbieri	46A
Mining industry; Report on non-ferrous —	207R	Detection of — by means of xanthic acid. Koppel	86A
Ministry of Mines Bill	240R, 294R	Determination of — in ferro-alloys	600A
Mists, artificial; Production of intense —. (P) Weiss and Verdier	469A*	Gravimetric determination of — as sulphide. Sterba-Böhm and Vostrebal	351A
Mixing and/or agitating machines. (P) Brinjes and Goodwin, Ltd., and Harris	564A	-iron alloys; Manufacture of —. (P) Deutsche Molybdaen-Werke	520A
apparatus:		Notes on —. Lambie	492A
(P) Brayman	216A	Qualitative and quantitative test for — in steel and iron. Malowan	27A
(P) Fiorini	590A*	Recovery of — from its ores. (P) Doerner	239A

apparatus; Combined vacuum drying and grinding or and —. (P) Ablett	436A	Molybdenite; Occurrence, detection, and determination of — in partly oxidised molybdenite ores. Bonardi	630A
apparatus for granular, powdered, or like material. (P) Bevin and Rawsthorne	179A*	<i>Momordia cochinchinensis</i> seeds; Fat of —. Corfield and Caird	163A
apparatus; Grinding and —. (P) Maddox	538A	Monazite sand; Decomposing —. (P) Chem. Fabr. Heiligensee Helholt u. Remse	191A
cacao, chocolate, or the like; Apparatus for —. (P) Postranecky	465A*	sand; Recovery of thorium from —. (P) Berndt, and Lindsay Light Co.	517A
calculations. Helbig	1A	Monel metal; Rapid analysis of —. Covitz	157A
and comminuting materials, e.g., alkali silicates. (P) Phillips and Rose	748A	Monoarylaminoquinones; Manufacture of —. (P) Becke and others	399A
of concrete aggregates and materials of a similar nature; Apparatus for dry —. (P) Lea	65A	Monoarylarsenious halides; Manufacture of —. (P) Pope	527A*
concrete ingredients or other substances; Machines for —. (P) Kiddle	217A*	Monoazo dyestuffs. See under Azo dyestuffs.	
gases and liquids. (P) Morawe	649A	Monobromoacetone; Manufacture of —. (P) Riedel A.-G.	385A
of gases with liquids or solids; Apparatus for intensifying the mutual action on the other during —. (P) Soc. Anon. l'Oxydrique Française	711A	Monobromoketones; Manufacture of —. (P) Riedel A.-G.	385A
and kneading machines. (P) Aeschbach A.-G.	324A*	Monochloroacetic acid; Continuous preparation of — from trichloroethylene. (P) Comp. Prod. Chim. d'Alais et de la Camargue	83A*
and like machines; Scrapers for use in —. (P) Shaw, and Shaw and Co.	356A*	α -Monoglycerides; Synthesis of —. Fischer and others	790A
liquid or semi-liquid materials; Apparatus for agitating, circulating, and —. (P) Coles, and Allen and Co.	144A	Mono- β -hydroxyethylaminobenzoate esters; Manufacture of —. (P) Soc. Chim. Usines du Rhône	280A
liquid, semi-liquid, or viscid materials; Machine for —. (P) Sonsthagen	2A	Montan wax; Behaviour of — towards ozone. Fischer and Tropsch	55A
liquids, gases, and the like. (P) Bruman	507A*	Determination of saponification value of —. Salvatore	220A
liquids and solids in powder or granular form. (P) Stier materials with fluids; Apparatus for —. (P) Loomis, and Arlington Co.	53A	Extraction of —. (P) Bollmann	577A
mills and the like; Means for discharging contents from —. (P) Orr	591A*	Production of — from lignite. (P) Riebeck'sche Montanwerke A.-G.	814A
mortar, concrete, and like material. (P) Candlot	65A	Resinous constituents of —. Marcusson	438A
oils and other liquids; Apparatus for filtering and/or —. (P) Cox	682A	Sizing paper by means of —. (P) Klemm	15A
operations; Means for feeding material through a rotating cylinder whilst subjected to —. (P) Sonsthagen	436A	Mordant salts; Dissociation of — by cellulose. Schwalbe Tintorial	58A
and sifting powdered and granulated substances; Apparatus for —. (P) Young	324A*	Mordanting value of tannins of galls, sumach, myrobalans, divi-divi, and quebracho; Relative —. Wisdom	293A*
Subjecting material to chemical treatment and grinding or and —. (P) Ablett	436A	Mordants; Manufacture of —. (P) Lopez and Quaglia	496A
Mixtures; Graphic calculations for —. Ostwald	321A	<i>Morinda citrifolia</i> ; Constituents of —. Simonsen	625A
of liquids; Apparatus for rapid preparation of homogeneous —. Jolibois	84A	Morine; Differentiation of quercitrin and —. Justin-Mueller	540A
Test for limit of incorporation in —. Perman	145R	Morocco; Minerals from —	816A
Moistening textile fibres and other materials. (P) Smethurst	61A*	Phosphate deposits in —	382R
Moisture content of cereals; Automatic indicator of —. Chopin	797A	Resources of —	320R
Determination of — in cereals. Nelson and Hulett	169A	Resources of Spanish —	96R
Determination of — in coal etc. Myhill	357A	Morphia; Supplies of —	221R
Determination of — in foodstuffs. Stutterheim and Lazet	499A	Morphine; Determination of — in opium. Jernstad	761A
Determination of — in solid materials. (P) McAllister in solid substrata; Relation of — to physiological salt balance for plants and to the relative plant-producing value of various salt proportions. Shive	708A	Determination of — in opium and its preparations. Rapp	425A
Molasses cane; Separation of potassium salts from coke or ash obtained from —. Von Stietz	243A	Mortar; Composition for and manufacture of waterproof —. (P) Badder and others	409A
cane; Sugar grain in final —: its origin and determination. Kalshoven	625A	Forming a covering or hardening coating on, or impregnating plastering of —. (P) Sanders and Sanders	599A
cane; Water content of true final —. Prijsen Geerligs	126A	-forming material; Manufacture of — from anhydrite. (P) Hartner	337A*
Determination of fine grain sugar in —. Von Lippmann	167A	Lime —. Kohlschütter and Walther	25A
	420A	Mixing —. (P) Candlot	65A
		Use of anhydrite for —. Hartner	573A
		Mortars made with cement, hydraulic lime, and volcanic ashes; Long-time tests of —. Hiroi	690A

and the like; Treatment of —. (P) Calvert	521A
Manufacture of catalysts for hydrogenating —.	
(P) Ellis	790A
(P) Moore, and Brown Co.	791A*
Richardson	459A
(P) Schuck	495A
Manufacture of edible and technical —. (P) Byk-Guldenwerke	522A
Manufacture of fullers' earth for refining of —. (P) Kohladorfer	72A
Manufacture of low-boiling — from higher boiling petroleum and related oils. (P) Cobb, and Standard Oil Co.	98A
Manufacture of pale, readily drying — from acid resins from refining of benzene. (P) Schümmer	633A
Manufacture of viscous —. (P) Börner	390A
Manufacture of viscous — readily converted into water-soluble products. (P) Tetralin Ges.	623A
Mineral —. <i>See under</i> Oils, Hydrocarbon.	
Neutralisation of —. (P) Arbini	551A
Neutralisation of — by esterification of the free fatty acid. (P) Schlinck und Co.	198A
Obtaining distilled products from —. (P) Stapp	98A
Obtaining semi-coke and — from coal in rotary distillation apparatus. (P) Fischer	56A
Production of fuel and lamp (solar) — from coal. Glund	223A
Production of — from peat, peat-straw, mosses, lichens, algae, grass, straw, pine-needles, and the like. (P) Von Porat	7A
Production of — from shale and other bituminous minerals. (P) Zeller und Gmelin	652A
Purification of —. Lach	376A
Rapid determination of water in —. Oertel	824A
Recovery of — from soap-free waste water. (P) N. V. Jurgens' Vereen. Fabr.	341A
Removal of catalyst poisons from — by means of fullers' earth prior to hydrogenation. Ueno	825A
Removing or decreasing objectionable odours from treated —. (P) Booge, and Du Pont de Nemours and Co.	450A
resistant to changes of temperature. Eisenstein	663A
Separating — from mixtures by means of continuous distillation and concentration columns. (P) Maschinenbau A.-G. Golzen-Grimma	742A
Separating light — from washing oil. (P) Koppers, and Koppers Co.	398A
Separating or separating and recovering (and if desired washing) — from water or other liquids. (P) Linden	287A
Shale —. <i>See under</i> Shale.	
Splitting — with germinating and resting castor seeds. Lalwala	340A
Splitting — for manufacture of glycerin and fatty acids. (P) Twitchell Process Co.	697A*
Splitting of — by means of castor seed lipase. Sudborough and others.	340A
Still for cracking —. (P) Gray	290A
Trade of Hongkong in —.	311R
Turbidity temperature of —. Parkes	145R
Oils, Essential:	
<i>Artemisia annua</i> oil; constitution of artemisia-ketone. Asahina and Takagi	832A
<i>Artemisia glutinosa</i> oil. Bennett	674A
Cassia oil; Rapid estimation of lead in —. Lubatti	35T
Cheopodium oil from various sources; Composition of —. Nelson	526A
Determination of cineol in —. Kleber and Von Rechenberg	763A
<i>Eucalyptus megacarpa</i> oil; Occurrence of terpinene in —. Smith	206A
Eucalyptus oil; Determination of cineol in —. Cocking	610A, 832A
Extracting — from peel of citrus fruits. (P) McDermott	765A
<i>Juniperus oxycedrus</i> oil; Chemical characters of —. Huere	467A
<i>Mosla grosseserrata</i> oil. Murayama	640A
Production of — in Spain	382R
Pseudo-iodine value of —. Huere	206A
Rose oil; German extracted —. Elze	43A
Rose oil (otto of roses) in Bulgaria	347R
<i>Rubiera multifida</i> oil. Nelson	527A
Sandalwood oil; Australian —	111R
Sandalwood oil in Western Australia	436R
Solvent for extraction of —. (P) Tetralin Ges.	665A
Tea leaf oil; Unsaturated alcohol of —. Van Romburgh	527A
Oils, Fatty:	
Animal oils; Value of — as sources of vitamin A. Drummond and Coward	798A
Arachis oil; Composition of fatty acids from —. Heiduschika and Felsner	272A
Arachis oil trade of Hongkong	44R
Boiled oils; Determining acid value of —. Gardner and Coleman	306A
Bottlenose oil. Fahrion	697A

Oils, Fatty—continued.

Reaction of — with charcoal. Lowry and Hulett	596A
Separation of air into nitrogen and —. Norton	721A
Use of — in gas production. Hodsman and Cobb	200B, 508A
-yielding detergents; Manufacture of —. (P) Möhring	418A
Oxyhydrogen gas; Catalysis of — by palladium mixed crystals. Tammann	515A
Ozokerite; Determination of paraffin wax in —. Koss	741A
Ozonisers; Electric —. (P) Franklin, and General Electric Co.	416A
Ozonising apparatus. (P) Bayeux and Richard	163A*

P

Packing; Heat-resisting —. (P) Stromeyer	274A
materials resistant to chlorine; Manufacture of —. (P) Wallace and Tiernan	214A
Tubular — for absorption apparatus. (P) Deutsche Ton- und Steinzeugwerke A.-G.	54A
Paint containers; Composition of air in —. Gardner and Rector	605A
Industry in Canada	347B
Industry; Candle-nut oils in the —.	105B
manufacture; Bulking values and yields of pigments and liquids used in —. Gardner and Parks	356B
media; Manufacture of antiseptic and preservative —. (P) Chem. Fabr. Flörsheim Noerdlinger	633A
oils suitable for cement and concrete; Manufacture of —. (P) Boehm, Ltd., and Reihl	241A
as a plastic material, not a viscous liquid; measurement of its mobility and yield value. Bingham and Green	495A
vehicles; Manufacture of — from mineral oils. (P) Soukup	728A
Painted articles; Drying —. (P) Cunliffe, and American Blower Co.	241A
Painting compositions; Manufacture of —. (P) Flakes A./S., and Schou	377A
Paints; Colloid chemistry of —. Morrell	73B
containing zinc oxide, linseed oil, and zinc oxychloride; Manufacture of —. (P) Witherich	633A
Hiding power of white —. Pfund	34A
Illumination from —. Gardner	72A
Instrument for measuring the hiding power of —. Hallett	632A
lacquer; Manufacture of quick-drying —. (P) Deutsch-Luxemburgische Bergwerks- und Hütten-A.-G., and Hilpert	792A
Manufacture of —. (P) Goldthorpe	35A*
(P) Isaacs	697A
(P) Koppers Co., and Darrin	757A*
(P) Schneider	757A*
(P) Wingen	522A*
Manufacture of antifouling — for ships' bottoms. (P) Arié	495A
Manufacture of — especially for use as undercoats. (P) Wright	241A
Manufacture of a substance suitable for producing durable — for wood. (P) Fuchs	665A
Manufacture of — from tar and slaked lime. (P) Klement	665A
for metals and other materials. (P) Ivinston and Roberts	757A*

	PAGE		PAGE
Paints—continued.		Paper—continued.	
for ships' bottoms etc. (P) Burstin	865A	Manufacture of —;	
Toxicity of lead —	169R	(P) Cedaroid Co.	103A
Waterproof —. (P) Kuroki and Makayama ..	35A, 342A*	(P) Imakoka	361A
Palestine; Vegetable oils in	95R	(P) Pope, and Great Northern Paper Co. ..	654A*, 719A*, 817A
Palladium; Ageing of colloidal —. De Rocasolano ..	626A	Manufacture of aluminium compounds for sizing —	
-black; Dehydrogenation of hydrocarbons by means of —. Tansz and Von Putnok ..	54A	(P) Muth	517A, 749A
-gold mixed crystals; Catalysis of oxyhydrogen gas by —. Tamman ..	515A	Manufacture of dense strong —. (P) Schwalbe ..	514A, 779A
Influence of hydrogen sulphide on occlusion of hydrogen by —. Maxted ..	782A	Manufacture of emulsions for sizing —. (P) Muth ..	361A
-silver mixed crystals; Catalysis of oxyhydrogen gas by —. Tamman ..	515A	Manufacture of hard-sized —. (P) Ruff	15A
Sorption of hydrogen by — at low temperatures. Firth ..	363A	Manufacture of size for —. (P) Mitscherlich ..	264A
Palm-kernel oil. See under Oils, Fatty.		Manufacture of — from textile fibres from raw plants. (P) Nesselbau Ges. ..	400A
Palm kernels; Restrictions on trade in —	18R	Manufacture of thread, twine, or cord from —. (P) Grant ..	153A*
Palmetto leaves; Commercial value of —	59R	manufacture; Treating sea-tang for —. (P) Frydensberg ..	16A*
Pancreatic amylase preparations; Proteolytic activity of —. Sherman and Neun ..	37A	Material for sizing — obtained from cellulose waste lyes. (P) Michl ..	779A
Panicum miliacum. See Proso millet.		Obtaining lignin substances suitable for sizing — from ligninsulphonic acids of sulphite-cellulose waste lyes. (P) Feldmühle Papier und Zellstoffwerke A.-G. ..	16A
Pantopon; Determination of total subsidiary alkaloids and of narcotine and papaverine in —. Anneler ..	800A	and paper fabrics; Rendering — grease- and water-proof. (P) Buchbinder ..	653A
Papaverine; Determination of — in opium preparations. Anneler ..	800A	paper pulps, and paper yarns and fabrics; Sizing and waterproofing —. (P) Fues and Braunnüller ..	653A
Paper; Apparatus for maklag —. (P) Murphy and others ..	14A	parchment; Manufacture of —:	
Apparatus for making ornamental —. (P) Mahler, and Kimberly Clark Co. ..	264A	(P) Dagnall	331A*
board; Manufacture of —:		(P) Hoering	653A
(P) Cedaroid Co.	103A	parchmentised; Manufacture of —. (P) Clayton and others ..	331A*
(P) Clapp, and Metalite Co.	361A	Perishing of — in Indian libraries. Sudborough and Mehta ..	93R
or board; Manufacture of easily folded —. (P) Volth ..	227A	Photographic —. See under Photographic.	
and boards; Sizing and waterproofing —. (P) Altmann ..	361A	plant in New South Wales; Government — ..	111R
Carbon — and ink composition thereof. (P) Ohashi ..	264A	production in Czechoslovakia	400R
-coating machines. (P) Mayer	60A*	Production of sewing or basting thread from —	
Colloidal rosin in beater sizing of —. Traquair ..	444A	(P) Vohwinkel Papier- u. Salicyl-Pergamentpapier-Ind. ..	226A
containing mucilage; Hygroscopic properties of —. Schwalbe and Becker ..	330A	pulp; Beating and refining engine for —. (P) Nash ..	686A*
Determination of dextrins in the presence of beater starch in —. Kamm and Tendick ..	102A	pulp; Colouring of — for textile purposes. Pfischel ..	12A
Determination of mixed pulp in newsprint — ..	12A	pulp; Colouring — with thiochlor dyestuffs. (P) Jäger ..	60A
Doll-head bearings for cylinders of drying machines for —. (P) Holt and Malone ..	153A*	pulp; Cooking cottonseed hull fibre for —. Kress ..	263A
Drying — in continuous strips. (P) Mallick ..	153A	pulp; Curtailment of bleaching powder consumption by addition of sulphur to digester liquor in manufacture of —. Spence ..	686A
Drying — in sheet form. (P) Minton ..	779A*	pulp; Dyeing — with insoluble artificial colouring matters. (P) Meister, Lucius, u. Brünig ..	331A
fabrics; Impregnating —. (P) Gebr. Heyl and Co. ..	104A	pulp; Engine-sizing of —. (P) Zellkoll Ges. ..	264A
fabrics; Improving —. (P) Exportingenieur für Papier- und Zellstofftechnik ..	185A	pulp from flax straw	443A
felt for roofing or the like; Manufacture of —. (P) Barrett Co. ..	361A*	and pulp industry in Canada	395R
Fixing and blackening pencil drawings on —. (P) Grünert ..	377A	pulp; Influence of temperature on rate of drainlug of — Smith ..	12A
Industries; Rendering waste from — absorbent. (P) Reis and Co. ..	185A	pulp; Machines for straining —. (P) Watford Engineering Works, Ltd., and Paramor ..	16A*
Industry in Canada	290R	pulp; Manufacture of —. (P) Skinner	227A
Industry in Italy	340R	pulp manufacture; Recovery of alkali from "black liquor" obtained in —. Moore ..	444A
and like containers; Impregnating — and subsequently draining. (P) Shirrow ..	331A*	pulp; Mucilage of parchment —. Selbst and Minor ..	686A
and the like; Continuous heating and refining engine for use in manufacture of —. (P) Nash ..	60A	pulp; Separators for —. (P) White	331A*
and the like; Machines for manufacture of —. (P) Thiry ..	654A*	pulp; Straining apparatus for use in manufacture of —. (P) Martin, and Lloyd, Ltd. ..	505A*
and the like; Production of a paste for manufacture of —. (P) Lottero ..	513A	pulp; Treatment of —:	
and the like; Sizing, waterproofing, dressing, etc. —. (P) Schmidt and Heuser ..	653A	(P) De Cew and Marx	153A*
Machines for drying varnished or gummed sheets of —. (P) Bush and Bush ..	445A*	(P) Howard	15A
Machines for impregnating —. (P) Mayer ..	361A*	pulp; Treatment of straw and the like for manufacture of —. (P) Werner ..	624A
Making lines and water-marks on —. (P) Suursalmi, and Kangas Pappersbruks Aktiebolag ..	186A	pulp; Tub beaters for —. (P) Griley-Unkle Engineering Co. ..	595A*
-making machines:		pulp. See also under Pulp.

textiles; Sizing and waterproofing — (P) Altmann	361A
textiles; Waterproof impregnation of — (P) Linke	103A
trade in South Africa	148R
for use as dielectric for electrical condensers and other purposes. (P) Haigh	292A
waste; Manufacture of cleaning material from — (P) Reis und Co.	15A, 227A
waterproof; Manufacture of —:	
(P) Clapp	595A
(P) De Cew	103A
(P) Kirschbraun	719A*
(P) Wandrowsky	779A
Waterproofing — (P) Böhme A.-G.	292A
yarn; Apparatus for drying — (P) Jagenberg	263A
yarn and cloth; Dyeing — (P) Chem. Fabr. Coswig-Anhalt	186A
yarn fabrics; Compacting — (P) Rawitscher	103A
yarn; Prevention of mould growth on — (P) Sarason	400A
yarn; Process for strengthening — (P) Ruff	15A
yarns and fabrics; Bleaching — (P) Jagenberg	400A
yarns and fabrics; Dyeing — with substantive colours. (P) Chem. Fabr. Coswig-Anhalt	154A
yarns or fabrics; Impregnating —:	
(P) Deutsche Pyroxytes.	445A
(P) Ruff and Praetorius	226A
yarns and fabrics treated with phenol-formaldehyde condensation products; Dyeing — (P) Ruff	229A
yarns; Softening — (P) Hasenbring	103A
yarns and textiles; Softening — (P) Bennert	330A
Papier-maché; Manufacture of pulp for making — (P) Skinner	227A
Papua; Natural petroleum from —. Read and Andrews	289T
Para cress; Splanthol, the pungent principle of —. Asahina and Asano	672A
Para Red. See under Azo dyestuffs.	
Para rubber seed oil. See under Oils, Fatty.	
Paracoumarone. See under Coumarone.	
Paraffin; Algebraic method for detecting — in cereals. Smeikus	358A
hydrocarbons; Uniform movement of flame in mixtures of air with —. Payman	95A
oil; Effect of addition of fatty acids on interfacial tension between mercury and —. Bhatnagar and Garner	185T
oils; Obtaining motor fuel and light — from shale. (P) Thurlow	539A
Oxidation of —. Kelber	220A
Producing cakes of solid crude — (P) Szekely	221A
Production of — from coal. Fischer and Glund	223A
Production of — from peat, peat-straw, mosses, lichens, algae, grass, straw, pine-needs, and the like. (P) Von Porat	7A
Thermal expansion of, and specific gravity of solutions of —. Von Piotrowski	5A
wax candles; Manufacture of —. Lach	775A
wax crystallising in scales; Purifying crude — by sweating. (P) Bartusch	716A
wax; Determination of — in ozokerite. Koss	741A
wax; Expressing — from petroleum distillates. (P) Wells and Wells	684A
wax; Extraction of — (P) Nichols, and Atlantic Refining Co.	814A
wax; Influence of high temperatures on —. Burstin and Jakubowicz	325A, 741A
wax; Manufacture of high-grade viscous lubricating oil and — from high-boiling fractions of gas-producer and low-temperature retort tars. (P) Allgem. Ges. f. Chem. Ind.	327A
wax; New sweating process for —. Székely	438A
wax; Oxidation of — by oxygen. Kelber	714A
wax; Refractometric determination of — as control test in manufacturing process. Freund and Palik	650A
wax; Separating — from mineral oils. (P) Sharples	682A
wax; Separating — in treatment of hydrocarbon mixtures with liquid sulphur dioxide. (P) Allgem. Ges. für Chem. Ind.	716A
wax; Separation of — from neutral oil and oxygen-containing constituent of producer- or low-temperature tar. (P) Allgem. Ges. für Chem. Ind.	652A
wax; Solid — found in Lancashire coal. Sinnatt and Barash	289A
wax; Synthesis of fatty acids from —. Löffl	604A
wax; Technique of crystallisation in manufacture of —. Fuchs	220A
Paraffins; Determination of — in commercial toluol: Colman	50T
Lewis	50T
Fatty acids obtained by oxidation of —. Fischer and Schneider	521A
Liquid — of lamp oil fraction of low-temperature coal tar. Fischer and Glund	223A
Oxidation of — to fatty acids etc. Grün	521A
Paraguay; Sugar industry in —	115R
Trade of — in 1919	348R
Paraldehyde; Determination of acetaldehyde in —. Stiwe	764A
Manufacture of — (P) Konsortium für Elektrochem. Ind.	467A
Manufacture of acetic acid from — (P) Soc. des Acériés et Forges de Firminy	527A

	PAGE
Paraldehyde—continued.	
Manufacture of ethyl acetate from — (P) Soc. des Acériés et Forges de Firminy	527A
Parasites; Destroying — and increasing germinating power of seeds. (P) Traube	759A
Parliamentary news. 18R, 79R, 96R, 100R, 116R, 135R, 151R, 186R, 205R, 223R, 239R, 258R, 278R, 294R, 361R, 384R, 401R, 419R, 439R	
Pasteboard; Drying — in continuous strips. (P) Mällekh	153A
Mechanical process for obtaining fibres for manufacture of — suitable for saturating with tar for roofings, linings, etc. (P) Kron	483A*
pulp; Engine-sizing of — (P) Zellkoll Ges.	264A
Pasteurisers and evaporators. (P) Ruff	733A
Pasteurising apparatus. (P) Buass	831A
liquids. (P) Mülertz	311A
Pasty materials; Apparatus for granulating or finely dividing semi-fluid or — (P) MacLachlan	39A
Patent rights; Italian — and the war	291R
rights; Prolongation of French —	74R
Patents; Chemical — with special reference to Canadian patent law. MacRae	109R, 176R
Patents and Designs Act, 1919	40R
Patents and Designs Acts, 1917 and 1919	117R, 172R
Patents and Designs Bill	19R
Patents, designs, and trade marks; Thirty-seventh report on — for 1919, by the Comptroller-General	292R
by Government servants	240R
Lists of —. 48A, 87A, 140A, 176A, 210A, 251A, 284A, 318A, 352A, 387A, 432A, 471A, 503A, 531A, 559A, 586A, 614A, 643A, 678A, 708A, 735A, 769A, 804A, 837A	
Proposed extension of life of German —	58R
in Sweden	291R
Paving material; Manufacture of fibrous — (P) Henderson	659A
materials; Manufacture of —:	
(P) Bünte and North	26A
(P) Honda	750A
and other purposes; Composition for — (P) Murray	193A
Peanut oil. See under Arachis oil under Oils, Fatty.	
Pea-pods; Fibrous material from — (P) Pöhler	185A
Pearl, mother of; Manufacture of glass resembling —. Schwarzbach	490A
Pearls, artificial; Manufacture of — and of jewellery. (P) Murakami	819A
Peas; Preserving — (P) Bruff	525A*
Peat; Action of various fertilisers made from —. Tacke	75A
Apparatus for extracting liquid from fresh — (P) Thäberg	773A
briquettes; Manufacture of — (P) Pasterer	55A
Carbonisation of — by treatment under pressure and heat in presence of liquids. (P) Billwiler	815A
Carbonising oven for — (P) Schröter	395A
Dehydrating —:	
(P) Bouillon	358A
(P) Hindshaw	358A
Determination of grade of —. Keppeler	394A
Disintegrating and extracting liquid from moist — (P) Melzer	565A
Distillation of — (P) Francke	56A
Driers for — (P) Jackson	358A
Extraction of — with dry and moist benzene under pressure. Fischer and Kleinstück	218A
fuel; Manufacture of —:	
(P) De Loog	776A*
(P) Edgeworth	622A*
(P) Neelsen	622A*
fuel; Manufacture of — from damp peat as dug from bog strata. (P) Davidson	5A
Gasifying — (P) Elektro-Osmose A.-G.	326A
Manufacture of ammonia and combustible gas or coke from — (P) Sauer	6A
Manufacture of cellulose from — (P) Hildebrandt	227A
mass; Treatment of — and production of briquettes. (P) Ullmann	714A
moss; Digestibility of — after treatment with acids. Godden	797A
moss fibres; Converting — into a condition suitable for spinning. (P) Deelen	330A
Preparation of damp — for manufacture of producer-gas. (P) Davidson	55A
Production of paraffin, waxes, oils, or fats from peat-straw or — (P) Von Porat	7A
resources of Ireland. Purcell	213R
soils; Hysteresis of aqueous solutions of —. Puchner	125A
Treatment of —:	
(P) Blair	684A
(P) Gruhl	558A
(P) Olsson	650A
in U.S.A. in 1918	148R
Wet-carbonising — (P) Testrup, and Wetcar-bonizing, Ltd.	56A
Pectins in various plants. Hornby	246T
Pelletierine. Tanret	638A
Pelt; Biological and chemical history of —. Relation of elastin to tanning process. Möller	36A

compounds; Manufacture of high-phosphorus pig iron and — from greensand. (P) Meadows	68A
compounds; Obtaining — from minerals. (P) Scholes, and Fry Glass Co.	192A*
compounds; Recovery of —. (P) Chemical Construction Co.	64A*
compounds; Recovery of aluminium compounds and — from greensand. (P) Hauber, jun.	63A
compounds; Recovery of — in connexion with cement manufacture. (P) International Precipitation Co.	367A
compounds; Recovery of — from minerals. (P) Messerschmidt, and Chemical Foundation, Inc.	571A
ferrieyanide; Electrolytic preparation of —. Brown and others	446A
ferrocyanide; Electrometric analysis with —. Müller formate; Manufacture of —. (P) Elektrochem. Werke Ges., and Strauss	45A
hydrogen phthalate as standard in alkalimetry. Dodge	833A
hydrogen phthalate as standard in volumetric analysis. Hendrixson	641A
hydroxide; Manufacture of —. (P) Higgins, and United Alkali Co.	530A
hydroxide solution; Manufacture of —. (P) Charlton, and American Potash Corp.	231A
iodate; Standardisation of — by means of sulphuric acid. Bertiaux	405A
Potassium nitrate; Manufacture of —. (P) Hampel	612A
Production of ammonium sulphate and — from potassium salts. Hampel	658A
Production of — in Chile	18A
Recovery of — from cement kiln gases and the like. (P) Chemical Construction Co.	221R
Retorts for decomposition of —. (P) Bayer und Co.	64A*
Potassium perchlorate; Caking of —. Lowry and Hemmings	656A
perchlorate; Manufacture of —. (P) Oberschlesische A.-G. für Fabr. von Lignose	105T
perchlorate; Manufacture of — by electrolysis of solutions of potassium chlorate. (P) Oberschlesische Sprengstoff A.-G.	571A
permanganate; Manufacture of — from ferromanganese by electrolysis. Thompson	571A
permanganate; Reaction between hydrochloric acid and —. Venable and Jackson	106A
permanganate; Side-chain oxidations with —. Bigelow	402A
phosphate; Reactions between primary — and increasing quantities of calcium bicarbonate during boiling. Windisch and Dietrich	8A
plumbite; Oxidation of — to potassium plumbate by alternating current. Jirza	486A
salts; Clarification of solutions of —. (P) Krupp A.-G. Grusonwerk	655A
salts containing kieserite; Obtaining sulphur from crude —. (P) Kiermayer, and Hannoversche Kaliwerke A.-G.	658A
salts; Crystallisation of — from solution. (P) Sauerbrey	406A
salts; Extraction of — from marine algae. (P) Darrasse Frères, and Dupont	449A
salts; Extraction of — from potash-bearing minerals. (P) Auden	499A
salts; Increasing the potash content of crude —. (P) Kiermayer, and Hannoversche Kaliwerke A.-G.	335A*
salts; Obtaining — from liquids containing the same. (P) Burnham	448A
salts; Obtaining — from saline waters. (P) Burnham	232A
salts; Production of ammonium sulphate and potassium nitrate from —. Hampel	232A
salts; Recovery of —. (P) McElhiney, and California Alkali Co.	18A
salts; Recovery of — from blast-furnace slag. (P) Bury and others	448A
salts; Recovery of borax and —. (P) Jacobi, and Pacific Coast Borax Co.	21A
salts; Recovery or purification of —. (P) Hirschkind, and California Alkali Co.	657A
salts; Separation of — from coke or ash obtained from cane molasses. Von Stietz	545A
salts; Separation of — from minerals. (P) Salzwirk Hellbronn, and others	625A
-sodium sulphate; Obtaining — from saline liquors. (P) Burnham	405A
Potassium sulphate; Exports and price of —	21A, 232A
Formation of double salts of calcium sulphate and — at 100° C. Anderson and Nestell	205R
Manufacture of —:	
(P) Dutt and Dutt	401A
(P) Fabr. de Prod. Chim. de Thann et de Mulhouse	63A
Potassium thiocyanate; Photochemical oxidation of —. Ganassin	516A, 689A
zirconium fluoride; Preparation of —. Marden and Rich	155A
Potato products; Manufacture of dried —. (P) Chem. Ges. Rheunania	596A
scab; Relation of sulphur to soil acidity and to control of —. Martiu	701A
starch. See under Starch.	667A

Tannin-albumin compound; Preparation of — from blood. (P) Knoll und Co.	467A
analysis; Baldracco and Camilla's modification of official shake method of —. Schell	660A
analysis; Modified method of —. Baldracco	123A
Parker	123A
analysis; Proteolytic factor in —. Moeller	730A
Diffusion process for extraction of — (P) Farkas	668A
Hamamelis —. Freudenberg and Peters	523A
-like constituent of coffee. Freudenberg	274A
-like material; Production of fibres capable of being spun, and a — from hop-bines. (P) Reis	13A
-lime compound difficultly soluble in dilute acids; Manufacture of —. (P) Tambach, and Chemical Foundation, Inc.	734A*
Manufacture of —. (P) Chem. Fabr. Grünau	793A
Landshoff und Meyer, and Schlein	729A
Quebracho —. Moeller	729A
substitutes; Manufacture of —. (P) Graf	419A
of sugar-cane; Nature of —. Zerbau	167A
Titration and estimation of — with iodine. Lee	496A
Tanning agents; Manufacture of —. (P) Schmidt, and Chemical Foundation, Inc.	419A*
agents; Manufacture of — from aminohydroxy-naphthalenesulphonic acids and formaldehyde. (P) Deutsch-Koloniale Gerb- u. Farbstoff-Ges.	378A
agents; Manufacture of — from <i>N</i> -arylsulpho derivatives of aromatic amino-sulphonic acids. (P) Ges. für Chem. Ind. in Basel	553A
agents; Manufacture of — from <i>N</i> - and <i>o</i> -aryl sulpho derivatives of aromatic amino and hydroxysulphonic acids. (P) Ges. f. Chem. Ind. in Basel	666A
agents; Manufacture of — from formaldehyde and aromatic derivatives. (P) Durand & Huguenin S.A. with aldehydes	308A
Gerngross	497A
Moeller	36A, 730A
with aldehydes; Formaldehyde titration of hide powder and —. Gerngross	730A
animal hides. (P) Chem. Fabr. Worms A.-G.	165A
animal skins. (P) Deutsch-Koloniale Gerb- und Farbstoff-Ges.	274A
Applications of chemistry in —. Wood	129R
Chamois —. Moeller	552A
Chrome —. Burton	666A
chrome-; Single-bath —. Griliches	633A
compound. (P) Levin	74A*
Degreasing hides and skins preparatory to —. (P) Krouse	497A
extracts; Detection of mangrove tannin in mixed —. Schell	496A
extracts; Detection of sugar in —. Grasser	418A
extracts; Detection of sulphite-cellulose in —. Knowles	242A
extracts; Manufacture of — from waste sulphite lye. (P) Landmark	200A*
extracts; Sugars in mimosa —. Harvey	242A
hides. (P) Ringhauer	666A
hides and skins. (P) Dufour and Dufour	165A

Tannins—continued.	
of galls, sumach, myrobalans, divi-divi, and quebracho; Relative affinity for cotton and mordanting value of —. Wisdom	496A
Phloroglucinol — and catechins. Freudenberg	729A
Synthetic —. Grasser	729A
Tannic acid; Solubility of gels of — and of tannic and niobic acids in mixtures of hydrogen peroxide and acid. Hahn and Gille	819A
Tantalum; Compressing powdered —. (P) Pfanstiehl, and Pfanstiehl Co.	30A
Tap; Metal-glass —. Garoer	347T
Tar acids. See Phenols.	
and ammonia recovery process for producer-gas. (P) Van Ackeren, and Koppers Co.	7A
coal; Diphenylene sulphide in —. Kruber	717A
coal; Extracting oils from —. (P) Comber and Stalker	184A
coal; Free carbon in —. Hodurek	622A
coal; Purification of — and recovery of high-molecular resinous bases. (P) Wirth	184A
coal; Resinous constituents of —. Marcussen	183A
coal; Separating thionaphthene from —. (P) Ges. für Teerverwertung	777A
coal; Thionaphthene in —. Weissgerber and Kruber	710A
Comparison of methods for producing gas and — from lignite. Holzwarth	683A
Determination of "free carbon" in —. Waterman and Barkhuysen	150A
Determination of — in gas. Stone and Prince	591A
Determination of nitrogen in —. Parker	507A
Determination of yield of — from coal. Fischer and Schrader	560A
distillates; Treatment of high-boiling coal — for production of resinous products. (P) Bailey and others	743A
distillation; Apparatus for continuous —. (P) Romberg	567A
distillation; Preheater for use in —. (P) Steinschneider, and Chemical Foundation, Inc.	814A
Effect of superheating on composition of —. Dolch	397A
Extraction of higher fatty acids and other organic acids from wood, lignite, or peat. —. (P) Börnstein	359A
Extraction of —, particularly of oil-tar, and de-resinification of resulting lubricating oils. (P) Röchlingsche Eisen- und Stahlwerke Ges.	327A
extractor apparatus and method. (P) Becker, and Koppers Co.	439A
extractors and scrubbers for gas. (P) Wells	813A
gas-producer; Manufacture of high-grade viscous lubricating oil and paraffin wax from high-boiling fractions of —. (P) Allgem. Ges. f. Chem. Ind. hydrocarbons; Fractional distillation plant for coal —. (P) Edwards	327A
industry in U.S.A. in 1919; Coal —.	328A
lignite; Action of concentrated and fuming sulphuric acid on fraction 200°-300° C. of —. Schneider and Jantsch	397R
lignite; Manufacture of highly viscous, combustible lubricating oils from —. (P) Deutsche Erdöl-A.-G. and others	291A
lignite; Production of benzene or petrol from — by cracking. Fischer and Schneider	182A
and the like; Separation of water and other impurities from —. (P) Billwiler	228A
low-temperature —. Fischer and Glund	815A
low-temperature; Behaviour of — from bituminous and non-bituminous lignite when distilled under ordinary pressure. Schneider	223A
low-temperature; Caloric value of gas formed in recovery of — in gas producers. Fischer	223A
low-temperature; Characteristic difference between — from lignite and other tars. Fischer and Schneider	96A
low-temperature coal; Liquid paraffins of lamp oil fraction of —. Fischer and Glund	224A
low-temperature coal; Phenols of —.	223A
I. Cresols. Glund and Brenner	150A
II. Catechol. Glund	151A
low-temperature coal; Properties and uses of products containing phenols obtained by direct distillation of —. Fischer and Glund	150A
low-temperature coal; Suitability of — for production of comarone-resin. Glund and Brenner	262A
low-temperature coal; Thickening of — and of its constituents. Fischer and others	223A
low-temperature; Discussion on economics of gas-producer plants operating with recovery of —.	478A
low-temperature; Economics of gas-producer plants operating with recovery of —. Roser	478A
low-temperature; Production of — from lignite and its use as a source of viscous oils. Schneider	222A
low-temperature; Production of — in steam-power plants. Wilkens	394A
low-temperature retort; Manufacture of high-grade viscous lubricating oils and paraffin wax from high-boiling fractions of —. (P) Allgem. Ges. f. Chem. Ind.	327A
low-temperature; Separating paraffin wax from neutral oil and oxygen-containing constituent of —. (P) Allgem. Ges. für Chem. Ind.	652A
low-temperature; Technically produced — from lignite. Schneider and Tropsch	222A

	PAGE
<i>Tar—continued</i>	
low-temperature; Yield of — from Arsa coal. Fischer	146A
Manufacture of illuminating gas and —. (P)	
Geyer	395A, 565A, 650A
Manufacture of resin solutions resembling varnish or gum from —. (P) McHardt	165A
Obtaining low-boiling hydrocarbons from —. (P) Schwarz	566A
Obtaining resinous bases from —. (P) Wirth, and Chemical Foundation, Inc.	815A*
oils; Agents for dissolving, separating, and extracting solid constituents of —. (P) Tetralin Ges.	653A
oils; Chemical constituents of bituminous — rich in sulphur. Scheibler	55A
oils for Diesel engines; Improving —. (P) Raschig	202A
oils; Isolation of active sulphur compounds of bituminous —. Scheibler	763A
oils; Manufacture of lubricating oils from —. (P) Klever	327A, 441A
oils; Obtaining neutral oil-like products from wash-lignors from treatment of —. (P) Wendriner	359A
oils; Production of viscous oils from non-viscous lignite — by heating in an autoclave. Schneider	223A
oils; Purification of heavy — and recovery of bases of high boiling point. (P) Wirth	184A
oils; Substitute for mineral oils from — for use in switches and transformers. (P) Tetralin Ges.	440A
oils; Uses of low-temperature lignite —. Harries	397A
oils; Utilisation of lignite —.	186R
paint; Manufacture of —. (P) Klement	665A
Phenol content of low-temperature and overheated —. Fischer and Brucer	261A
Preheaters for use in distillation of —. (P) Steinschneider	261A*
producer; Separating paraffin wax from neutral oil and oxygen-containing constituent of —. (P) Alkern. Ges. für Chem. Ind.	652A
products; Export licences for coal —.	223R
products; Imports and exports of —.	440R
products; Manufacture of coal —. (P) Weiss, and Barrett Co.	743A
products; Manufacture of quick-drying varnish from —. (P) Deutsch-Luxemburgische Bergwerks- u. Hütten A.-G., and Hilpert	577A, 665A

textile; Manufacture of durable —. (P) Müller and Herzberg ..	103A
Waterproofing —. (P) Böhme A.-G. ..	292A
windings; Apparatus for drying —. (P) Jagenberg ..	263A
Yeast; Acid formation by —. Boas and Leberle ..	168A
Action of chloroform on —. Bertrand and Rosenblatt ..	498A
Adaptability of — to different temperatures. Zikes ..	203A
Alcoholic fermentation by —. Köhler ..	732A
Analysis of —. Vautier ..	38A
Applications of reducing action of — in wine making. Mathieu ..	309A
Autolysis of — in its dependence on hydrogen and hydroxyl ions. Dornby ..	129A
Catalytic decomposition of hydrogen peroxide by —. Phragmén ..	107A
cell; Influence of surface-active nonyllic acid and amyl and octyl alcohols on the —. Windisch and others ..	701A
cells; Behaviour of dyes towards —. Von Euler and Florell ..	244A
Characters of — as it occurs in nature. Jørgensen ..	129A
Chemical isolation of vitamins from —. Myers and Voegtlin ..	500A
Degeneration and treatment of —. Hens ..	609A
Effect of organic and inorganic substances on fermentation of —. Masters and Maughan ..	796A
Enzymic activities of —. Bokorny ..	202A
Extraction and concentration of vitamin of —. Osborne and Wakeman ..	131A
Factors which interfere with use of — as test organism for the antineuritic substance (vitamin B). Souza and McCollum ..	830A
fat; Nature of —. MacLean and Thomas ..	604A
fermentation; Sulphurous acid and —. Hägglund ..	580A
-foods ..	131R
Formation of fat in — on solid media. Lladner and Unger ..	129A
Growth of — in alkaline solutions. Von Euler and Svanberg ..	245A
growth-promoting stimulus; Relation of water-soluble, anti-neuritic, and water-soluble B vitamins to —. Emmett and Stockholm ..	671A
Influence of sudden cooling, during or after fermentation, on —, especially in respect of subsidence. Will ..	462A
Influence of temperature on various functions of —. Zikes ..	830A

Yeast—continued.

Influence of temperature and acidity on formation of invertase from —. Von Euler and Svanberg ..	463A
Invertase and fermentation enzymes in top —. Von Euler and Möberg ..	244A
-like fungi; Action of ultra-violet light on —. Feuer and Tauer ..	636A
Maltase solutions from —. Willstätter and others ..	760A
Manufacture of —. (P) Verein der Spiritus-Fabrikanten in Deutschland ..	381A
Manufacture of — from fermented musts, particularly fermented musts of molasses and sugar beet pulp. (P) Dupire ..	701A
Manufacture of foods or stimulants for promoting growth of — in bread making. (P) Geere and Geere ..	556A
Manufacture of nutrient —, especially for use as nitrogenous fodder, from waste waters of sugar factories. (P) Riedel ..	761A
Manufacture of pressed —. (P) Verein der Spiritus-Fabrikanten in Deutschland ..	345A
Manufacture of pressed — from worts containing little or no sugar. (P) ..	168A
Manufacture of rubber-like or leather-like masses from formaldehyde and —. (P) Blücher and Krause ..	242A
Manufacture of — from seaweed. (P) Bayer and Orlajensen ..	499A
Manufacture of — using waste beetroot pressings and other expressed saccharine liquids. (P) Reinke ..	796A
Manufacture of — with little or no production of alcohol. (P) Verein der Spiritus-Fabrikanten in Deutschland ..	345A, 463A
masses; Extraction of fat from —. (P) Kriegsausschuss für pflanzl. u. tier. Öle und Fette ..	756A
Nitrogen metabolism in <i>S. cerevisiae</i> . Lampitt ..	669A
nucleic acid; Structure of —. Levene ..	246A
nucleic acid; Structure of —. Ammonia hydrolysis. Levene ..	133A
nutrition and fermentation. Bokorny ..	795A
Precipitating — in fermented liquids, especially fermented worts of aero-yeast factories. Verein der Spiritus-Fabrikanten in Deutschland ..	245A
Preservation of —. (P) Robertson ..	245A
Production of — for fodder. (P) Verein der Spiritus-Fabrikanten in Deutschland ..	246A
Production of formic acid by — in media containing amides. Thomas ..	421A
protein; Manufacture of medicinal preparations from basic dyestuffs and —. (P) A.-G. Haaf and Co. ..	833A
Rhythmic phenomena in growth and fermentation of —. Köhler ..	732A
<i>Saccharomyces thermantimonum</i> ; Characters of — after prolonged cultivation. Von Euler and Laurin ..	555A
Sensitiveness of living — towards hydrogen and hydroxyl ions. Von Euler and Emberg ..	202A
Stimulating fat-formation in —. (P) Kriegsausschuss für pflanzliche u. tierische Öle u. Fette ..	168A
Treating waste brewers' — to render it suitable for baking purposes. (P) Anderschou ..	701A
Treatment of brewers' or distillers' — to obtain a food product resembling meat extract. (P) O'Sullivan and others ..	39A
Utilisation of amides by —. Thomas ..	77A
See also under <i>Saccharomyces</i> .	
Yellow A B and O B. See under Azo dyestuffs.	
Yellow-tail fish oil. See under Oils, Fatty.	
Yohimbin and nucleic acid; Manufacture of readily soluble compounds of —. (P) Weinert ..	765A
Yucca; Treating — for recovery of fibres. (P) Loehr ..	292A
Ytterbium earths; Separation of terbium and —. Meyer and Müller ..	333A

Z

Zinc; Allotropy of —. Bingham ..	560A
or its alloys; Coating metallic surfaces with —. (P) Berlin-Burger Eisenwerk A.-G. ..	303A
Alloys of copper, nickel and —. Guillet ..	269A
alloys; Manufacture of —. (P) Goldschmidt and others ..	457A
(P) Kammerer ..	372A
(P) Tedesco, and Stabilimenti Biak ..	695A
alloys; Study of cast — with special reference to their use as bearing metals. Glen ..	158A
alloys; Utilisation of German supplies of pyrophoric —. Guertler ..	67A
alloys; Utilisation of waste pyrophoric —. Czochralski and Lohrke ..	630A
-aluminium alloys; Improving the mechanical properties of —. (P) Heddernheimer Kupferwerk u. Süddeutsche Kabelwerke ..	415A
-aluminium-copper alloy; Corrosion of a screw fitting made of —. Bauer ..	661A
-aluminium-copper alloys. Rosenhain and others ..	109R, 370A
-aluminium-copper alloys rich in zinc. Schula and Wachert ..	369A
-aluminium-copper; The ternary system — with special reference to the zinc corner of the equilibrium diagram. Jares ..	67A

Zinc—continued.	PAGE
Aluminothermic process of obtaining corundum and —. (P) Kohle und Erz Ges.	662A
Analysis of commercial —. Olivier	660A
battery elements; Electrolytic production of —. (P) Copper-Coles	696A*
-bearing ores; Treatment of —. (P) Cameron and others	695A
blende; Roasting —. (P) Fellner und Ziegler, and Von Escher	302A
Calculation of chemical constants of —. Branne	548A
concentrates; Electric furnace for reducing oxidised — by carbon. (P) Thomson	29A
concentrates; Government purchase of Australian — concentrates; Roasting — in suspension. Fulton and Read	439R
content of reagents and apparatus. Weitzel	660A
-copper alloys; Magnetisability of —. Weber	317A
-copper alloys prepared by melting or by electro-deposition; Chemical and electrochemical properties of —. Sauerwald	661A
and copper; Constituents formed by interpenetration of — at temperatures below melting points of the metals and their alloys. Weiss	575A
-copper-lead alloys; Manufacture of —. (P) Arend	117A
-copper ores; Treatment of complex —. Hommel	160A
Detection of manganese and — in presence of phosphates and oxalates. Schmidt	530A
Determination of — in organic materials, e.g., urine, faeces, foods, etc. Weitzel	317A
distillation; Determination of quantity of gas evolved during —. Mühlhauser	752A
distillation process; Utilisation of residual ash from —. (P) Schlesische A.-G. für Bergbau u. Zinkhüttenbetrieb	662A
dust; Influence of foreign gases on formation of — during condensation of zinc vapours. Ravner	786A
dust; Rotary electric furnaces for continuously melting —. (P) Corneliuss	725A
Experimental determination of vapour pressure curve of molten —. Braune	548A
Extraction of —. (P) Berglund and Huld	303A*
Extraction of — from galvanised iron in the open-hearth furnace, with recovery of zinc oxide. Müller	693A
Extraction of lead and — from ores. (P) Elmore	603A*
furnace; Combustion chamber of the Hegeler —. Mühlhauser	300A
furnace refractories. Audley	237A
furnaces; Determination of thermal conditions of —. Mühlhauser	412A
industry in Australia	304R
industry in France	167R
industry in Japan	289R
-lead alloys. (P) Falkenberg	725A
-lead-copper ores; Treatment of complex —. Hommel	160A
and lead deposits of Gaspe. Beidleman	70R
-lead ores; Treatment of complex —. Hommel	160A
-manganese alloys. Siebe	27A
Manufacture of alloys of lead, copper, and —. (P) Vereinigte Hüttenwerke Burbach-Eich-Düdelingen A.-G.	161A
Manufacture of alloys of lead, copper, tin, and —. (P) Vereinigte Hüttenwerke Burbach-Eich-Düdelingen A.-G.	161A
Manufacture of good workable — from inferior material. (P) Siemens-Schuckertwerke Ges.	372A
Measurement of minimum thickness of deposits of — by their electromotive force. Procopiu	116A
mines in Finland	258R
muffles; Colouring matter formed in old fragments of — and changes due to muffle and furnace gases. Mühlhauser	454A
ore; Manufacture of briquettes of — suitable for smelting. (P) Schlesische A.-G. für Bergbau u. Zinkhüttenbetrieb	662A
ores; Electric resistance furnace for treatment of —. Fulton	193A
ores, residues, and ashes; Utilisation of low-grade —. Wolbling	66A
output of Canada	112R
Polishing and etching of — for micro-examination. Hayes	300A
production; Methods for analytical control of electrolytic —. Bradley	338A
production of U.S.A. in 1919	113R
Reactions of metallurgy of —. Lemarchands	338A
Recovery of copper and — from burnt pyrites. (P) Reisenegger	662A
Recovery of — by electrolysis. (P) Stevens, and Electrolytic Zinc Co. of Australasia Proprietary, Ltd.	31A*, 725A
Recovery of — from low-grade and complex ores. Lyon and Ralston	194A
-reduction furnace. (P) Shipton	754A
Refining —. (P) Nestmann	372A
refining process; Effluent —. (P) Johnson	339A
Retort furnace for recovery of — by reduction of zinc oxide. (P) Bursitzky	69A
-retort residues; Working up —. (P) Eichhorn	270A
retorts; Determination of thermal conditions of charge in —. Mühlhauser	752A
retorts; Influence of pressure in — on output of metal. Mühlhauser	66A

Zinc—continued.	PAGE
retorts; Microstructure of —. Scott	237A
retorts; Permeability of —. Mühlhauser	300A
Separating — from burnt pyrites. (P) Bayer und Co.	662A
Separating and recovering cadmium and —. (P) Leibniz smelting in Norway	788A
Solubility of — in cyanide solutions. White	322R
solutions; Purification of —. (P) Field, and Metals Extraction Corp.	371A
(P) Salm and others	372A, 373A*
solutions; Treatment of —. (P) Petersson, and Metals Extraction Corp.	823A
sulphide ores; Roasting — preparatory to leaching. (P) Electrolytic Zinc Co. of Australasia Proprietary, Ltd.	823A
Theoretical principles underlying metallurgy of —. Jänecke	492A
Treatment of residues containing copper, cadmium, and —. (P) Elton and others	549A
Treatment of zinc-bearing ores for recovery of — by electro-deposition. (P) Gepp and others	31A*
Treatment of zinc solutions preparatory to recovery of — by electro-deposition. (P) Avery and others	603A*
Volumetric estimation of —. Houben	85A
wire; Producing an alteration of structure of — by heating during winding. (P) A.-G. Brown, Boveri, und Co.	458A
See also Spelter.	
Zinc chloride; Manufacture of —. (P) Storey, and Burgess Laboratories	722A*
compounds; Manufacture of pure — from impure materials. (P) Bayer und Co.	109A
compounds; Manufacture of soluble — from roasted zinc ores. (P) Reisenegger	406A
oxide; Manufacture of —. (P) Breyer and others	22A
(P) Singmaster and others	22A
oxide; Manufacture of hydrogen and —. (P) McKee	819A
oxide, phosphorus pentoxide, and water; The system — at 25° and 37° C. Eberly and others	595A
oxide pigments; Manufacture of —. (P) American Zinc, Lead, and Smelting Co., and Wemple	123A*
oxide plant in Canada	147R
oxide; Recovery of — by treatment of galvanised iron in the open-hearth furnace. Müller	693A
oxide-sodium oxide-water; Equilibrium in the system —. Gondrian	155A
oxide; Treatment of —. (P) Breyer and others	489A
oxide; Treatment of zinc and zinc-containing materials for production of —. (P) Maconochie and De Ros	448A
phosphates. Eberly and others	595A
sodium sulphate; Manufacture of —. (P) Bayer und Co.	109A
sulphate solutions; Purification of —. (P) Comp. Prod. Chim. d'Als et de la Camargue	294A
sulphide; Fusion of —. Tiede and Schleede	747A
sulphide; Influence of crystalline form, flux, and actual fusion on phosphorescence of —. Tiede and Schleede	747A
Zirconia; Separating — from ores and minerals. (P) Gordon	657A
-silica; Approximate determination of melting-point diagram of system —. Washburn and Libman	628A
Zirconium; Determination of —. Smith and James	768A
Determination of — by the phosphate method. Lundell and Knowles	46A
Determination of — in steel. Lundell and Knowles	574A
-lead alloys; Manufacture of —. (P) Petinot, and U.S. Ferro-Alloys Corp.	415A
Manufacture of — from its ores or oxide. (P) North and Loosli	788A
Metallic —. Marden and Rich	596A
minerals; Analysis of —. Thompson	180R
ore; Analysis of Brazilian —. Powell and Schoeller	67A
Separation of iron, aluminium, chromium, glucinum, titanium, and — by means of sodium carbonate. Wenger and Whrmann	46A
Separation of titanium and — as phosphates. Brown and Madden	316A
-steel; Manufacture of —. (P) Sicard, and U.S. Ferro-Alloys Corp.	415A
-titanium-iron alloys; Manufacture of —. (P) Sicard, and U.S. Ferro-Alloys Corp.	415A
Zirconium carbide; Manufacture of alloys containing —. (P) Petinot, and U.S. Ferro-Alloys Corp.	415A
compounds; Manufacture of —. (P) Barton, and Titanium Alloy Manufacturing Co.	517A
monoxide; Question of existence of —. Schwarz and Delsler	62A, 230A
oxide; Manufacture of —. (P) Barton, and Titanium Alloy Manufacturing Co.	689A
oxide; Preparation of —. Marden and Rich	596A
potassium fluoride; Preparation of —. Marden and Rich	596A
sulphate, basic; Manufacture of —. (P) Pennsylvania Salt Manufacturing Co.	820A*
Zostera marina fibre; Manufacture of a material for deadening sound and other purposes from —. (P) MacFarland and others	337A
Zygosaccharomyces capable of fermenting concentrated sugar solutions. Satava	420A

List of New Books and other Publications Received.

Mineral industry of British Empire and foreign countries.	
War period:	
Arsenic	264R
Iorates	314R
Chrome ore and chromium	298R
Felspar	298R
Fuller's earth	298R
Magnesite	298R
Monazite	314R
Nitrates	314R
Mineral oil; Treatise on British —. Greene (Ed.) —	101R*
Mineral resources of Great Britain; Special reports on —:	
VI. Refractory materials: ganister and silica rock; sand for open-hearth steel furnaces; dolomite ..	210R
XV. Arsenic and antimony ores. Dewey, Flett, and Wilson	210R
XVI. Refractory materials etc. Petrography and chemistry. Thomas, Hallimond, and Bradley ..	332R
Mineralogy of rarer metals. Cahen and Wootton (revised by Cahen)	84R
Molasses; Reading list on —. West	332R
Nitrogen Products Committee. Munitions Inventions Department. Ministry of Munitions of War; Final report of —.	46R
Nomenclature des journeaux, revues, periodiques français	24R
Nucleic acids: their chemical properties and physiological conduct. Jones	406R
Oil analysis: Short handbook of —. Gill	66R
Oils; Commercial vegetable and animal —. Laueks ..	24R*
Oils, fats, and waxes; Animal and vegetable —. Martin ..	192R, 298R*
Ore analysis; Technical methods of —. Low	282R, 367R*
Organic chemistry. Killen Macbeth	332R
Organic chemistry for advanced students. Cohen	406R
Organic chemistry; Class book of —. Vol. II. Cohen ..	66R
Organic chemistry; Laboratory manual of —. Fisher ..	448R
Organic chemistry; Text-book of —:	
Barnett	264R
Hollemaa	448R
Organic chemistry; Treatise on general and industrial —.	
Part I. Molinari (translated by Pope)	448R
Organic compounds; Preparation of —. Barnett	121R*
Ozone. Rideal	246R
Pauchromatism	174R
Patent law of all countries; Handbook of —. Thompson ..	388R
Peat resources of Ireland. Purcell	228R
Pharmacopœia; The extra —. Vol. I. Martindale and Westcott	246R, 349R*
Pharmacopœia of the United States; Digest of comments on — and on the National Formulary for 1915 and 1916. Du Mez	350R
Pharmacy; Year-book of —, and transactions of the British Pharmaceutical Conference, Liverpool, 1920	448R
Phase theory; Principles of the —. Clibbens	350R
Photographic researches of Hurter and Driffield. Ferguson (Ed.)	122R, 210R*
Physical chemistry; System of —. Vol. II. Thermodynamics. Lewis	424R
Physical and inorganic chemistry; Recent advances in —. Stewart	388R
Platinum metals. Lumb	424R
Platinum; Production of — for 1919. Kunz	388R
Practical chemistry; Elementary —. Part I. General chemistry. Clowes and Coleman	24R
Precious stones; Production of — for 1919. Kunz	388R
Public health chemical analysis. Foister and Frederick ..	406R
Report of Committee of Privy Council for Scientific and Industrial Research, 1919-1920	333R
Reports of Society of Chemical Industry on progress of applied chemistry; Annual —, 1919. Vol. IV. ..	174R
Research; Notes on chemical —. Draper	246R
Research organisations; Reports of first and second conferences of —.	174R
Rubber calculator book; Bamber's —	424R
Rubber; Plantation —, and testing of rubber. Whitby ..	368R, 405R*
Saccharin; Ueber die Kontrolle n. Herstellung von —. Beyer	122R
Salt deposition; Principles of —. Geology of non-metallic mineral deposits other than silicates. Vol. I. Grabau	424R
Scientists' reference book and diary, 1921	418R
Service chemistry. Lewes and Brame	66R
Sewage disposal. Kinnicutt, Winslow, and Pratt	66R*
Standards; British chemical —	246R
Steel-works materials; Chemical analysis of —. Hibbottson	332R, 406R*
Sucrier; Annuaire —, 1919-1920	46R
Sugar-cane; Manual experiments with —. Tempny ..	24R
Sugar; Manufacture of — from the cane and beet. Ifieriot	332R, 421R*

Tobacco; Further trials with cultivation and manufacture of Réunion —. Tempny and Auchinleck	24R
United States Bureau of Mines publications:	
Accidents at metallurgical works in U.S.A. during 1918. Fay	424R
Aluminum alloy casting; Blowholes, porosity, and unsoundness in —. Anderson	424R
Anthracite; Burning steam sizes of — with or without admixture of soft coal ..	122R
Automobile exhaust gases; Vitiating of garage air by —. Burrell and Gauger ..	122R
Boiler and furnace testing. Strom	424R
Carbon dioxide and oxygen in air and flue-gases; Indicators for —. Milligan, Crites, and Wilson	350R
Clays; Properties of some stoneware —. Schurecht	350R
Coal mine fatalities in U.S.A. in 1919. Fay ..	264R
Coal mines; Dangerous and safe practices in bituminous —. Steidle	156R
Coal; Safe storage of —. Stock	264R
Experiment Stations of Bureau of Mines. Manning	350R
Explosives; Development of liquid oxygen — during the war. Rice	264R
Explosives; Production of — in the United States. Fay	156R
Gasoline left in residual gas from compression plants; Absorption as applied to —. Dykema and Neal	424R
Gasoline; Motor —; properties, laboratory methods of testing, and practical specifications. Dean	122R
Gasoline; Recent developments in absorption processes for recovering — from natural gas. Dykema	84R
Gold, silver, copper, lead, and zinc in Arizona in 1918. Heikes	156R
Gold, silver, copper, lead, and zinc in Eastern States in 1918. Hill	156R
Gold, silver, copper, lead, and zinc in Idaho and Washington in 1918. Gerry	156R
Gold, silver, copper, lead, and zinc in Nevada in 1918. Heikes	156R
Gold, silver, copper, lead, and zinc in New Mexico and Texas in 1918. Henderson ..	156R
Graphite; Mining and preparing domestic — for crucible use. Dub and Moses ..	448R
Illinois mining statutes annotated. Thompson ..	84R
Manganese. Weld and others	448R
Mining and mineral industry; Glossary of —. Fay	424R
Molybdenum; Determination of —. Bonardi and Barrett	350R
Oil wells; Decline and ultimate product of —. Beal	84R
Oil wells; Perforated casing and screen pipe in —. Wagy	264R
Petroleum and allied substances in 1916; Bibliography of —. Burroughs	84R
Petroleum investigations and production of helium. Manning	84R
Petroleum; Removal of the lighter hydrocarbons from — by continuous distillation. Wadsworth	350R
Quarry accidents in the United States during 1918. Fay	264R
Rocks; Determination of combustible matter in silicate and carbonate —. Fieldner, Selvig, and Taylor	84R
Stenches; Uses of — as a warning in mines. Katz, Allison, and Egy	448R
War gas investigations. Manning	122R
Zinc; Recovery of — from low-grade and complex ores. Lyon and Ralston	84R
United States Geological Survey publications:	
Abrasive materials in 1918. Katz	406R
Arsenic, bismuth, selenium, and tellurium in 1918. Hill	24R
Asbestos in 1918. Diller	174R
Asphalt and allied substances in 1918. Osborn ..	174R
Barites and barium products in 1918. Stone ..	314R
Bauxite and aluminum in 1918. Hill	264R
Building operations in the larger cities in 1918. Middleton	24R
Cadmium in 1918. Siebenthal	282R
Chromite in 1918. Diller, Bliss, Aldrich, and Burchard	282R

United States Geological Survey publications— <i>continued</i> .	PAGE
Clay-working industries, siliceous brick, and building operations in larger cities in 1918. Middleton ..	406R
Coal in 1917. Part B. Distribution and consumption. Leshner ..	24R
Coal in 1918. Part A. Production. Leshner ..	314R
Cobalt, molybdenum, nickel, titanium, tungsten, radium, uranium, and vanadium in 1917. Hess ..	424R
Cobalt, molybdenum, tantalum, titanium, radium, uranium, and vanadium in 1918. Hess ..	496R
Concrete, stone, and building blocks: Architectural— in 1917 and 1918. Loughlin ..	174R
Copper in 1917. Butler ..	282R
Copper in 1917. (General report). Butler ..	314R
Copper in 1918. Butler ..	424R
Felspar in 1918. Beach ..	314R
Fluorspar and cryolite in 1918. Burchard ..	122R
Gasoline: Natural gas —, Sleivers ..	406R
Gold and silver in 1918. Dunlop ..	406R
Gold, silver, copper, and lead in South Dakota and Wyoming in 1918. Henderson ..	24R
Gold, silver, copper, lead and zinc in California and Oregon in 1918. Yale ..	264R
Gold, silver, copper, lead, and zinc in Colorado in 1917. Henderson ..	264R
Gold, silver, copper, lead, and zinc in Eastern States in 1918. Hill ..	122R
Gold, silver, copper, lead, and zinc in New Mexico and Texas in 1917. Henderson ..	24R
Iron ore, pig iron, and steel in 1918. Burchard ..	264R
Lead in 1917. Siebenthal ..	282R
Lime in 1918. Loughlin and Insley ..	496R
Magnesium in 1919. Stone ..	424R
Manganese and manganiferous ores in 1917. Hewett ..	24R

United States Geological Survey publications— <i>continued</i> .	PAGE
Manganese and manganiferous ores in 1918. Hewett ..	264R
Mica in 1918. Schaller ..	314R
Mineral production of United States in 1917. McCaskey and Clark ..	496R
Mineral resources of United States in 1916. Part I. Metals. Part II. Non-metals ..	350R
Mineral resources: Work on — done by U.S. Geological Survey. Bastin and McCaskey ..	174R
Mineral waters in 1918. Ellis ..	174R
Nickel in 1918. Hess ..	406R
Peat in 1918. Osborn ..	24R
Peat in 1919. Cottrell ..	406R
Platinum group metals: Bibliography of —, 1748-1917. Howe and Holtz ..	350R
Potash in 1918. Hicks ..	174R
Quicksilver in 1918. Ransome ..	24R
Rocks: Analysis of silicate and carbonate —, Hillebrand ..	350R
Sand and gravel in 1918. Stone ..	24R
Silica in 1918. Catz ..	122R
Stone in 1918. Loughlin and Coons ..	424R
Strontium in 1918. Stose ..	174R
Talc and soapstone in 1918. Diller ..	174R
Thallium, zirconium, and rare earth minerals in 1919. Schaller ..	424R
Verre: Le soufflage du — dans les laboratoires scientifiques et industriels. Vigreux ..	264R
Volatile oils. Vol. II. Gildemeister and Hoffmann (translated by Kremers) ..	388R
Water: Chlorination of —. Race ..	46R, 156R*
Writing: Art of technical —. Rickard ..	448R
Yeasts. Guillermond (translated and revised by Tanner) ..	424R

List of Patents Abstracted.

List of Journals Abstracted, with Abbreviations Used, and Addresses of Publishers and Prices.

JOURNAL.	ABBREVIATION.	ADDRESS OF PUBLISHER AND PRICE.*
Agricultural Bulletin of the Federated Malay States	Agric. Bull. F.M.S. ..	Dept. of Agriculture, Kuala Lumpur, F.M.S. \$1.5.
Agricultural Journal of India	Agric. J. India ..	W. Thacker and Co., 2, Creed Lane, London. 3s.
Agricultural Ledger ..	Agric. Ledger	Reporter on Economic Products to the Government of India. Calcutta.
Agricultural Research Institute, Pusa, Report and Bulletins	Rep. (Bull.) Agric. Res. Inst., Pusa.	Supt. Govt. Printing, Calcutta. Price varies.
Allgemeine Zeitschrift für Bierbrauerei und Malzfabrikation	Allgem. Z. Bierbrau.	Michaelerstrasse 25, Vienna XVIII/1. 150 fr. per annum.
American Journal of Pharmacy.	Amer. J. Pharm. ..	145, North Tenth Street, Philadelphia, Pa., U.S.A. 30 cents.
American Journal of Science	Amer. J. Sci.	New Haven, Conn., U.S.A. 50 cents.
Anales de la Sociedad Española de Física y Química	Anal. Soc. Espan. Fis. Quim.	D. M. T. Gil, Corredera Baja de San Pablo, num. 59, Madrid. 15 pesetas per annum.
Anales de la Sociedad Química Argentina	Anal. Soc. Quim. Argentina	1790, Lavalle, Buenos Aires. 60 c
Analyst	Analyst	Simpkin, Marshall, Hamilton, Kent and Co., Ltd., 2, 4, 6, 8, Orange Street, London, S.W. 3s.
Annalen der Chemie	Annalen	C. F. Winter'sche Verlagshandlung, Leipzig, Germany. M. 60 per annum.
Annales de Chimie	Ann. Chim.	Imprimerie Gauthier-Villars et Cie., Quai des Grands-Augustins, 55, Paris. 40 fr. per annum

List of Errata, 1920.

No. of Journal.	Page.	Column.	Line from top.	Line from bottom.	Corrigenda.
No. 1—Jan. 15 ..	24A	1	—	38	For "Anderson" read "Andersen."
No. " 2—Jan. 31 ..	35A	1	—	28-29	Delete "(B)(C) Substitutes for celluloid, vulcanite or the like."
" " " ..	19T	2	—	—	In the "Softening" graph, curve C refers to high-grade, not to low-grade balata.
" " " ..	61A	1	12-13 and 17	—	For "anthocyanins" read "anthocyanins."
" " " ..	71A	1	4	—	For "polarising" read "depolarising."
" " " ..	74A	2	2	—	For "1,328,878" read "1,323,878."
No. 3—Feb. 16 ..	97A	2	—	—	Line 16 from top should follow line 13.
No. 4—Feb. 28 ..	170A	1	24	—	For "Manual" read "Menaul."
" " " ..	175A	2	—	4	For "Constantino" read "Constantino."
No. 5—Mar. 15 ..	66T	1	25	—	Replace by "which are relished by cattle, but it is doubtful."
" " " ..	196A	1	—	19	For "Gallet" read "Gallot."
No. 7—Apr. 15 ..	136R	2	22	—	This line should read: "Canadian trade in period Jan. 1919 to Jan. 1920. During this period Canada."
" " " ..	136R	2	34	—	Delete "in 1920."
No. 8—Apr. 30 ..	309A	2	—	24	For "Matthieu" read "Mathieu."
No. 9—May 15 ..	322A	2	20	—	For "1,322,657" read "1,332,657."
No. 11—June 15 ..	197R	1	—	—	In bottom line, for "35" read "115."
" " " ..	203R	2	—	—	In last two columns of table, for "1917-18" and "1918-19" read "1918-19" and "1919-20."
" " " ..	430A	1	—	20	For "Fieldler" read "Fiedler."
No. 12—June 30 ..	215R	2	33	—	For "J. R. McLellan" read "J. C. McLennan."
" " " ..	215R	2	—	29	For "McLellan" read "McLennan."
No. 13—July 15 ..	476A	1	25	—	For "1,324,417" read "1,340,653."
" " " ..	489A	1	—	33	For "Burdick . . . 29.1.29" read (A) 1,339,544 and (B) 1,339,545, 11.5.20. Appl. 9.8.18."
No. 14—July 31 ..	195T	1	—	41	For "all cases" read "many cases."
" " " ..	195T	2	19	—	For "quality" read "gravity."
" " " ..	195T	2	—	19	For "40%" read "50%."
" " " ..	196T	1	—	29	For "100 cb. ft." read "1000 cb. ft."
" " " ..	196T	2	34	—	After "gaseous B.Th.U." insert "This may amount to as much as 1s. per gallon of motor spirit."
" " " ..	224T	2	3-5	—	For "His experience . . . corrosion" read "Lead stored in the open became severely carbonated in a short time after heavy rains, but this was not the case with lead containing perhaps 0.5% Cu."
No. 15—Aug. 16 ..	557A	1	31	—	For "Rappel" read "Ruppel."
No. 16—Aug. 31 ..	563A	1	9	—	For "Waite" read "Wait."
No. 20—Oct. 30 ..	696A	2	7	—	For "on Schlegell" read "Von Schlegell."
No. 22—Nov. 30 ..	396R	1	—	17	For "professional" read "professorial."
" " " ..	765A	1	—	6	For "Boehninger" read "Boehringer."
No. 23—Dec. 15 ..	415R	2	—	13	For "carbonisation" read "carbonatation."
" " " ..	802A	1	7-8	—	For "Trimethyl-m-cresotic" read "Trimethylacetyl-m-cresotic."
" " " ..	804A	1	33	—	For "Z. Anal. Chem., 1920, 59, 297-302" read "Helv. Chim. Acta, 1920, 3, 652-653."
No. 24—Dec. 31 ..	432R	2	17	—	For "G. F. Morrell" read "R. S. Morrell."
" " " ..	813A	2	—	5	For "Allen" read "Allan."
" " " ..	818A	2	17	—	For "Jäcke" read "Jänecké."
" " " ..	830A	2	17	—	For "Basset" read "Bassett."

MR. JULIAN L. BAKER IN THE CHAIR

THE TECHNICAL APPLICATIONS OF ETHYL CHLORIDE.

BY ALBERT HENNING.

The manufacture of ethyl chloride dates back to 1500 A.D., and the earliest reference which can be traced appears to be that of Basil Valentine, who refers to it in his book, "Wiederholung des grossen Steines der uralten Weisen," ed. Petreus, p. 72. From the description given it is evident that the product, "Spiritus salis et vini," could not have been pure ethyl chloride, and was probably a mixture of spirit with ethyl chloride, containing about 10% of the latter. Reference to ethyl chloride was also made by Glauber (1648), who referred to the fact that spirit digested for a long time with muriatic acid "kills its sal volatile" and a "fine clear oleum vini swims to the top."

The production of ethyl chloride in the pure state was probably first achieved between 1820 and 1830, but in 1871 Genther (Zeits. für Chemie, 1871, p. 147) stated that ethyl chloride was not obtainable as a commercial product, and that for research work he found it necessary to prepare it for himself.

COMMERCIAL PRODUCTION OF ETHYL CHLORIDE.

Whilst, at first, ethyl chloride was prepared almost entirely for medical purposes, the technical application has become so extensive as to demand larger production, and before the war, in one factory alone in Germany, the production of this material was as much as 250,000 kilos. per annum, whilst in another factory the output was 80,000 kilos., and other factories were producing rather smaller quantities. The product was chiefly used for ethylation in the manufacture of dyestuffs and drugs. Further quantities were also produced for use as a refrigerant and as a solvent. In the United States there are four factories making ethyl chloride, and France and Switzerland also produce very large quantities.

Considering the low price of ethyl chloride compared with other ethylating agents, these figures are not in any sense surprising, and although the English manufacturers of ethylated products are persistently demanding ethyl sulphate and other ethylating agents, none of these can compete with ethyl chloride.

The accompanying table shows the comparative cost of various ethylating agents under normal conditions, and the approximate cost per 1 lb. of ethyl radical. From these it will be seen that as an ethylating agent ethyl chloride is the cheapest agent by about 60%, and it is necessary to examine at some length the properties of ethyl chloride, which have a bearing upon its application in manufacture, and to ascertain whether the material possesses such properties as will counterbalance the advantage of cheapness.

	Approx. cost per lb.	C.H ₅ "	Approx. cost 1 lb. C ₂ H ₅ .

PROPERTIES OF ETHYL CHLORIDE.

The commonest of all misconceptions regarding ethyl chloride is that it must be stored in high-pressure cylinders, and handled substantially in the same manner as a compressed gas, such as oxygen or hydrogen. As a matter of fact, the material may be siphoned or poured by means of jugs in transferring from one vessel to another.

The scale on which ethyl chloride is manufactured in this country may be judged from the fact that a 950 gallon tank is used for storage of ethyl chloride freed from methyl.

The subjoined table shows the absolute pressure of saturated ethyl chloride vapour between -30° C. and +100° C. In order to estimate the gauge pressure which will be operative in the production of bursting stresses in containing vessels, it is necessary to deduct the pressure of the atmosphere, viz., 14·7 lb. per square inch or 76 cm. mercury column.

Temp.	Absolute Pressure. Cm. Mercury	lb. per sq. in.	Temp.	Absolute Pressure. Cm. Mercury	lb. per sq. in.
-30°C. ..	11-02 ..	2-13	35°C. ..	164-32 ..	31-77

0° ..	46-52 ..	9-00	65° ..	387-85 ..	74-98
+5° ..	56-93 ..	11-00	70° ..	440-50 ..	85-16
10° ..	70-09 ..	13-55	75° ..	498-27 ..	96-33
12-5° ..	76-00 ..	14-70	80° ..	561-40 ..	108-50
15° ..	83-26 ..	16-10	85° ..	630-16 ..	121-80
20° ..	99-62 ..	19-26	90° ..	704-75 ..	136-30
25° ..	118-42 ..	22-90	95° ..	785-39 ..	151-80
30° ..	139-90 ..	27-05	100° ..	872-28 ..	168-60

Under normal conditions of storing and handling in this country, it is extremely unlikely that the containers would be subjected to a higher temperature than +30° C., and even at this temperature the gauge pressure is only 12 lb. per square inch. It is the common practice to store samples of ethyl chloride for reference in ordinary corked bottles for a period of several years, and several Winchester bottles fitted with ordinary corks and without any other fastenings have shown practically no loss after six years' storage. It is fairly obvious, therefore, that this material should be regarded rather as a volatile liquid than as a liquefied gas, and that elaborate high pressure apparatus is wholly unnecessary. The railway regulations in this country are somewhat elastic. They provide that ethyl chloride should be sent out either in fragile glass containers, packed in cotton-wool and cardboard boxes, or in welded steel drums tested to a pressure of 66 lb. per square inch. From the pressure curve it is fairly obvious that ordinary ether drums capable of resisting a pressure, under test, of 40 lb. per square inch would be quite satisfactory, and, in fact, for ordinary factory purposes these are used in regular practice.

Although ethyl chloride is volatile, owing to its high latent heat, it evaporates only slowly when exposed. The following table shows the actual losses by evaporation of ethyl chloride from an open vessel. A "pony" glass 3½ in. deep and 2 in. diameter at

the mouth was partly filled with 115 grms. of ethyl chloride and allowed to stand in a room at 11° C. and evaporate spontaneously. The b.pt. of this sample was 9°-12° C.

Time in minutes	Gross weight Grms.	Total loss Grms.	Over successive intervals.		
			Time in minutes.	Loss Grms.	Loss per minute Grms.
Start	177.5	—	—	—	—
10	174.5	3.0	10	3	0.30
50	168.5	9.0	40	6	0.15
*150	156.5	21.0	100	12	0.12
310	135.5	42.0	160	21	0.13
360	132.0	45.5	50	3.5	0.07

* For ninety minutes during this period the vessel was kept in a warm room at 14°-15° C. on a mantelpiece directly over a gas fire, during which time it lost 1.4 grms.

After a small proportion of the bulk has evaporated the temperature of the remainder is reduced to +7° to 8° C., when further loss is comparatively slow, and the following quantitative experiment shows how the liquid may be handled in open vessels in the laboratory.

About 2650 c.c. of ethyl chloride was removed from 50 c.c. bottles and filtered through an ordinary 20-cm. paper fitted in a plain funnel. As the corks were cemented in, each one had to be dug out, with consequent mechanical loss. In spite of all factors entering to facilitate losses, the amount collected at the end of the trial was 2100 c.c. This transference took about two hours, and the loss shown is surprisingly small when it is noted that the vials were not cooled in any way, but when opened were at a temperature of 18° C. If they had been cooled by ice before opening the losses would have been negligible.

Similarly, ethyl chloride can be manipulated in ordinary laboratory apparatus without special precautions, and 10 litres of solution has often been extracted with 2 litres of ethyl chloride without the use of cooling agents or special apparatus.

It is commonly stated that ethyl chloride is very readily combustible, and in consequence an undesirable material to deal with in large quantities. Whilst it is undoubtedly inflammable, its high latent heat of vaporisation, combined with the circumstance that the mixture of ethyl chloride and air is only inflammable over a comparatively narrow range of composition renders the material no more dangerous to handle than methylated spirit or benzol. There would be no danger involved in smoking a cigarette near an open vessel containing ethyl chloride, and a lighted cigarette if dropped into a beaker full of ethyl chloride is extinguished. Mention may also be made that liquid ethyl chloride is not ignited by the sparks on the commutator of electrical machines. A spray of the liquid projected from a leak or a small hole will not burn, except in immediate contact with a flame.

The application of ethyl chloride as a refrigerant has become extensive in America, and the experience with the material for these purposes has been such that the National Board of Fire Underwriters has approved its use. This decision was reached after a special investigation had been carried out by Professor Jacobus, of the Stevens Institute of Technology, who was appointed by the Board of Underwriters as their independent expert (see "Ice and Refrigeration," December, 1908, p. 311).

The Navy Department of the United States was furnished with ethyl chloride for making tests on their Proving Ground. The report of these tests was decisive. In fact, the experts at the Proving Ground were inclined to ridicule the idea of a chemical of this kind being sent to them for test of explosive force. We have had 200 cubic feet of ethyl chloride vapour accidentally liberated in an enclosed space within 20 feet of two lighted boilers without accident.

Ethyl chloride, unlike other chlorinated solvents of similar type, is entirely without poisonous properties, and in this respect it possesses a very marked advantage over ethyl sulphate, which is a most treacherous material in works practice. The application of ethyl chloride as an anæsthetic has, however, given rise to the impression that soporific effects are liable to be produced in workpeople handling it, but this is an entirely mistaken impression. For the production of anæsthesia, the application must be made under very definite and carefully regulated conditions, and by means of an airtight face-piece or mask. A small leakage of air past the face-piece is sufficient to prevent anæsthesia, and, as a result, complaints are occasionally received that material supplied for anæsthetic purposes had been found unsatisfactory in practice. Such complaints are generally traceable to leakage. In the course of handling, by means of a staff of girls, hundreds of thousands of tubes, and filling these with ethyl chloride, no single case of accidental anæsthesia has ever been observed. The use of ethyl chloride as a local anæsthetic constitutes sufficient proof of this statement. A surgeon will spray ethyl chloride on to the chin or lip of the patient and yet general anæsthesia is not produced.

In the case of a staff of twenty girls sitting in one room of about 2500 cubic feet, handling ethyl chloride freely, the vapour being constantly present in the atmosphere, no complaint has ever been received; but, on the contrary, newcomers generally state that the work has a bracing effect and induces a better appetite. An open fireplace is used in this room.

Ethyl chloride holds but the very slightest trace of water, and, compared with ether, this advantage is most marked for solvent or extraction purposes. The statement that 10 parts of ethyl chloride will dissolve in 100 parts of water is often taken as meaning parts by weight. Actually this refers to volumes of ethyl chloride *gas*, which makes the solubility only 1 part in 3000 by weight. This is negligible for most purposes. It must not be taken that the best ethyl chloride on the market contains even this amount, since every care is taken to ensure the product being anhydrous and free from ether. Such a product, as stated later, can be safely used in contact with any metal without fear of corrosion.

TECHNICAL APPLICATIONS OF ETHYL CHLORIDE.

The principal applications of ethyl chloride are:—

- (1) In the synthesis of dyestuffs and drugs as an ethylating agent.
- (2) As a working substance in refrigerating machinery.
- (3) As a solvent for extraction purposes.
- (4) In research work and in laboratory practice.

In addition, ethyl chloride is, of course, used for medical purposes, but these applications do not come within the scope of this paper.

Application as an ethylating agent.

The importance of the ethyl group is not generally realised, and there is found in literature and

also in research work a persistent tendency to refer to the more expensive methyl derivatives as intermediate products. It is obvious, from the point of view of cost of raw materials alone, that a methyl derivative must be more expensive than the corresponding ethyl derivative, unless there is some special difficulty in the manufacture of the latter.

The import statistics of the United States show that the value of typical ethylated colours (including only those colours the constitution of which is known) imported before the war into the U.S. amounted to over £75,200 per annum. In addition to this amount, very considerable allowance must be made for ethylated colours included under the unclassified list, and also for a proportion of the direct colours, which are generally sold under names indicating that they are derivatives of diaminidine, but which are really derivatives of the cheaper ethoxybenzidine. For the production of these colours two outstanding processes are involved: (a) Ethylation of the amino group. (b) Ethylation of the hydroxyl group.

(a) The first type of transformation can often be produced by heating the salt of the amine in an autoclave with pure ethyl alcohol. In this reaction the salt must be a haloid salt, and therefore generally the use of an enamel-lined autoclave is necessary. In the application of other ethylating agents the difficulty experienced is, in general, the purification of the ethylating agent; and, in fact, if even comparatively small proportions of methyl compounds be present, the shade of the colour produced is considerably modified. Ethyl chloride may be used for this purpose, and has a distinct advantage in that it is a material which can be produced commercially in an exceptionally high state of purity, and whereas the ordinary commercial ethyl chloride contains a high percentage of methyl chloride, a special quality for ethylation is now available in large quantities in this country which contains less than 0.1% of methyl chloride. As to the method of ethylating amino compounds with ethyl chloride, it is, of course, impossible to generalise; but it may be stated that with suitable apparatus the reaction may be carried out in ordinary cases in about four hours, in an autoclave capable of withstanding a working pressure of about 150 lb. per square inch. The advantage is very marked when compared with the procedure necessary in the case of ethylation with ethyl alcohol. In the latter case a much more substantial autoclave is necessary, an enamel lining is essential, and the speed of operation will bear no comparison.

(b) The ethylation of hydroxy compounds is carried out by substantially the same methods, and in this case ethyl chloride is the standard agent in technical use. The process of ethylation of hydroxy compounds has received special attention as a means of increasing the fastness to alkalis of hydroxyazo colours, particularly *p*-hydroxyazo colours, in which the deficiency in fastness is very noticeable; as an example of this transformation the conversion of Brilliant Yellow into Chrysophenine may be cited. In reactions of this kind it is always necessary to use an ethylating agent, and the price of ethyl chloride has naturally rendered its application universal.

In this country, the necessity for using an autoclave with ethyl chloride has been considered a serious objection to its application, and leanings towards ethyl sulphate have been noticeable, under the impression that this material would overcome all the chemical engineering difficulties involved. In Germany, before the war, we find that the sulphate was not in anything like general use, the chloride having been easily able to hold its own. The information given below regarding the tech-

nique of ethylation with ethyl chloride will show that the product is perfectly safe and simple to handle upon the large scale, provided reasonable intelligence is exercised.

FIG. 1.

Pure ethyl chloride is now issued in drums provided with the special fastening shown in Fig. 1. By means of the devices shown, a valve may be screwed into position as soon as the drum is ready for use, this valve being provided with a serrated edge, which cuts through the lead sealing disc shown. The ethyl chloride may then be transferred either direct into the autoclave or into a measuring vessel (see Fig. 2). In this vessel a charge of ethyl chloride may be measured off, and by manipulation of the taps shown the contents transferred to an autoclave, which need not be cooled prior to the introduction of the charge. By means of these devices leakage of ethyl chloride is completely obviated, and cooling of the autoclave, such as is necessary in the ordinary methods of manipulation in using alcohol and other agents, is avoided.

FIG. 2.

It has been stated that ethyl chloride presented unusual difficulties in autoclaves, owing to leakage through the stuffing-box. This difficulty is nearly always due to the wrong kind of packing having

been employed. Since ethyl chloride is a solvent for every kind of oil, wax, or grease, ordinary paraffined asbestos packing cannot remain in good condition for more than a few minutes. If, however, the packing be filled with fibre impregnated with glycerin the same difficulty is not experienced, as ethyl chloride does not dissolve glycerin.

An arrangement whereby leakage of ethyl chloride through the stuffing-box may be entirely counteracted consists (see Fig. 2) of a simple packing-box having double packing, the space between these being connected with the condensing vessel shown, so that the pressure on the outer packing may be reduced to practically zero, *i. e.*, to the difference in pressure between the vapour pressure of the ethyl chloride in the condensing vessel and the atmospheric pressure. In the arrangement shown the condensing vessel also serves as a filling vessel. These devices are the subject of a patent application.

For some operations it is possible to use an autoclave of the rotating type, and since nearly all the ethylations with ethyl chloride take place below 100° C., it is possible to use a simple stationary jacket type such as that shown in Fig. 3. In this case, since there is no stuffing-box under pressure, no leakage can occur. When the ethylation is finished, it will generally be found that the pressure has fallen to a low value, and that there is practically no ethyl chloride left, so the emptying of the autoclave will present no difficulties whatever.

FIG. 3.

By means of the devices mentioned above ethyl chloride may be used without the slightest leakage occurring, and with far less difficulty than would be experienced in using an autoclave with alcohol. In the case of alcohol, fairly elaborate precautions are necessary in order to avoid loss, owing to the high temperature necessary to induce reactions, and in the case of ethyl sulphate the poisonous character of the material constitutes in itself a difficulty, which may not at first be realised.

The great advantage of ethyl chloride above all other ethylating agents is that, owing to its low boiling point, it can be secured commercially in a very high state of purity, and, whereas nearly all other materials for the same purposes are liable to contain considerable percentages of methyl compounds, ethyl chloride is now marketed practically free from methyl chloride. The influence of methyl chloride upon the shade of the dyestuff produced is marked, and in the case of synthetic drugs the methyl compounds are generally regarded as more toxic.

Application as a solvent.

Ethyl chloride possesses marked advantages, shared to some extent by methyl chloride, for use in the extraction of various natural products. Ethyl chloride dissolves nearly all organic compounds with great readiness, and, in the case

of comparatively volatile compounds, the low boiling point of ethyl chloride renders its application particularly advantageous. Ethyl chloride of ordinary commercial quality is anhydrous, and where it is necessary that the dry solute should be extracted its use is indicated, especially if the solute is sensitive to heating.

This matter of temperature may be of great importance where a substance is easily decomposed, and it may be instanced that nitrosamines prepared from secondary amines can be easily extracted and recovered from ethyl chloride solution without decomposition.

As to its solvent power, the following indications may be given:—Monohydroxy compounds such as phenol are soluble, as are acids like benzoic acid, but when both hydroxyl and carboxyl groups are present, as in salicylic acid, the solubility is greatly diminished. A second hydroxyl group has the same effect, resorcinol and quinol being practically insoluble. The carbinol group follows the rule for the hydroxyl groups, for, although propyl alcohol is easily soluble, glycerol is not. Introduction of successive halogen groups into a compound does not decrease the solubility, but tends to increase it. The presence of nitro groups diminishes the solubility of a compound in ethyl chloride.

Oils and fats are readily dissolved. In fact, experiments have been made successfully with flowers, herbs, seaweed, mosses, and even seeds and nuts, in extracting the oil and other substances.

In many operations in which extraction processes are used, it is necessary to freeze, usually by means of cooled brine, in order to cause crystallisation of certain constituents of the extract. When ethyl chloride is used as a solvent this procedure is quite unnecessary, because the extracted material may be obtained at a temperature as low as -15° to -20° C. by simply evaporating off the ethyl chloride under a slightly reduced pressure. The application of this principle to the isolation of pure compounds from essential oils is specially advantageous, and the ethyl chloride lends itself to recovery more easily than any other solvent. In this direction it would appear that considerable development is likely, and that where products of a high degree of purity are required it may become almost universal. For extraction purposes ethyl chloride possesses a distinct advantage over all other chlorinated solvents, in that it does not tend to become acid on storage if properly stabilised in manufacture. A sample after several years' storage under the action of light developed no trace of acid.

Application in refrigeration.

Before discussing the application of ethyl chloride refrigeration, it is necessary to review the physical data available, and in this paper will be given for the first time a complete set of figures suitable for use in the design of refrigerating machinery.

The accompanying table has been specially calculated from the meagre physical data available; it shows the vapour pressure, latent heat, specific volume, etc., for this purpose. The figures in the next table have been calculated from these to show the general order of magnitude of the essential features of various classes of refrigerating machinery, using carbon dioxide, ammonia, sulphur dioxide, methyl chloride, and ethyl chloride. The upper line of the table gives the relative cylinder dimensions based upon the assumption that piston compressors are used, operating at the same speed for a definite amount of refrigeration, and the figures in the lower portion indicate the working

pressures on the evaporation and compression sides of each system. From this it will be noticed that whereas ethyl chloride, for a given amount of refrigeration, requires a much larger compressor, the range of pressures required is extremely low. This pressure range is, in fact, so low that for all ordinary purposes the disadvantage of the large displacement is entirely counteracted, because instead of using an elaborate reciprocating compressor, one may employ a simple rotary pump, not very different in construction from the well-known gas exhausters.

† Absolute pressures in atmospheres.

Refrigerator cars fitted with ethyl chloride machines are not by any means a recent innovation. The machine is operated from the car axle by means of a belt drive, arrangements being provided for compensation when the car passes over curved portions of the track.

Fig. 4.

An additional advantage for small machines is that the pump may be driven directly from a small motor without the use of any reduction gear, and this cannot be said for small plant using other refrigerants. By way of giving a general idea of dimensions of ethyl chloride machines, it has been

found in practice that with cooling water at 65°F . an 18-in. diameter rotary pump having a rotor 12 in. wide, running at 150 to 300 revolutions per minute, is equivalent to a five-ton ice machine; in operating such a machine the highest pressure in the system is 15 lb. per square inch, and the pumps will even give a sufficient pressure to operate the machine using cooling water above 90°F ., and yet maintain a sufficiently low pressure on the evaporation side of the system to cool down as far as -15°C . Whilst in this country ethyl chloride is practically unknown as a refrigerant, in America this business has been developed very considerably—more than 150 plants are working—and, in fact, the U.S. naval authorities are using ethyl chloride machines on their warships. On the Hanover Bank Building of New York an ethyl chloride refrigerating plant has been working over nine years, and on the U.S.S. "Dakota" over eight years. The French naval authorities have also had several vessels fitted with similar plants. Other countries likewise have fitted their naval vessels with ethyl chloride refrigerating machines, and are increasing the number of installations of this type.

A very promising development in ethyl chloride refrigeration is found in its application to very small plant, suitable for ordinary household use, and having in general a refrigeration capacity of about 500 kilo-calories per hour. A machine of this description is readily driven directly coupled

Fig. 5.

to a quarter H.P. motor; Figs. 4 and 5 show the general construction of two types of machine. In using other refrigerants in small machines, it is found that the small size of the various connecting pipes, and particularly of the expansion valves, renders regulation almost out of the question, whereas, in the case of the ethyl chloride machine, in which much larger volumes are handled for a given performance, the fittings may be made of convenient practical size, and regulation is easily within the capacity of inexperienced people. For household use, an ammonia or a carbon dioxide machine would be dangerous, owing to the high working pressure necessary, and the consequent skilled supervision required. In the case of ethyl chloride the highest pressure encountered will be about 15 lb. per square inch, and consequently the machine is safe to use. All the connecting pipes, condenser tubes, etc., may be of the lightest material, and may be made of steel or copper.

Owing to the low pressure involved, the necessity for brine circulation does not occur, and if we consider the application of ethyl chloride refrigeration to ordinary chemical purposes, it may be seen that, whereas in certain cases where corrosion of cooling coils is likely to occur, the direct circulation of ammonia or carbon dioxide would not be attractive, for example, in a cooling vessel for some corrosive liquid, ethyl chloride, by virtue of its low pressure range, might well be circulated without danger direct in the cooling coils of the vessel, and there would be no difficulty in using lead coils for this purpose in practice. In the case of ammonia or carbon dioxide this would be impossible. It may be thought, at first sight, that no advantage could accrue from the direct circulation of the working substance in such coils, but since a refrigerating machine is a reversed heat engine, the efficiency, *i.e.*, the number of calories absorbed for a given amount of power put into a machine, depends upon the value of the factor $(T_2 - T_1)/T_1$, approximately, where T_2 = absolute temperature of the condenser coils and T_1 = absolute temperature of the refrigerator coils. This is a consequence of Carnot's theorem.

Such coefficients of performance are shown in the table; it will be seen that by maintaining a temperature of, say, 20° F. it is only possible to get half the output obtained with a working temperature of -10° F.

Coefficients of performance of a perfect refrigerating machine.

Lower limit. of temperature, °F	Upper limit of temperature, ° F.					
	50°	60°	70°	80°	90°	100°
-10°	7.5	6.4	5.6	5.0	4.5	4.1
0°	9.2	7.7	6.6	5.8	5.1	4.6
10°	11.7	9.4	7.8	6.7	5.9	5.2
20°	16.0	12.0	9.6	8.0	6.8	6.0
30°	24.5	16.3	12.2	9.8	8.2	7.0
40°	50.0	25.0	16.7	12.5	10.0	8.3

Now, in order to maintain a temperature of 20° F. by brine circulation it would be necessary to use brine which had been cooled before pumping into the cooling vessel at 10° F., or possibly even 0° F., and it is obvious, therefore, that the heat is being absorbed under conditions which do not compare favourably with the direct circulation system. No doubt for some purposes direct circulation of ammonia or carbon dioxide would be possible, but in chemical works, where corrosion is likely to occur and liability to disaster must be avoided, the properties of ethyl chloride render its application worthy of serious consideration. It is noteworthy that the direct circulation of ethyl chloride may be made in coils or jackets constructed in acid-resisting materials which are deficient in mechanical strength.

Ethyl chloride for laboratory use and in research work.

Few efforts have formerly been made to supply ethyl chloride in convenient packages for laboratory purposes. It is now, however, issued in such a manner as to be generally available for research work, and it is hoped that greater confidence in using this material will be the result. Ethyl bromide, iodide, and sulphate are expensive materials for use as laboratory reagents, and the results obtained with them are not representative of good technical practice.

The application of ethyl chloride in the laboratory as a solvent possesses many favourable

features, and for laboratory purposes in which small quantities are required at a time, ethyl chloride is now issued in glass siphons similar to the well-known sulphur dioxide siphon, and in cheap and handy metal cylinders. These inexpensive containers are most convenient for laboratory work, as the piece of lead tubing may be cut off and a rubber fitted with a screw clip fixed over the open end. These kind are not liable to breakage as are glass containers, and are inexpensive in every way.

For experimental purposes in ethylation, ethyl chloride is now issued in hermetically sealed tubes containing 2, 5, or 7 c.c. of ethyl chloride; and the 7 c.c. tubes contain 0.1 gm.-mol. of pure ethyl chloride. These tubes may be dropped into an autoclave unbroken, and when the temperature rises they will burst, or the capillary tubes may be broken off before they are put in the autoclave, provided the tubes are cooled slightly before this is done. By means of these special tubes an experimental ethylation, or several simultaneous experiments, may be conveniently carried out, very much after the same fashion as analytical work is now often done with compressed tablets of the various reagents.

The low boiling point of ethyl chloride makes it a very convenient cooling agent for laboratory work. When allowed to emerge through a capillary jet, or an injection needle, it is capable of producing a very low temperature, and small objects may readily be reduced to as low as -30° C. For cooling small quantities of reaction mixtures, such as those obtained in diazotising, or inducing crystallisation, or in the preservation of biological specimens, the laboratory vessels containing ethyl chloride will be found convenient.

The use of ethyl chloride in hygrometers is also convenient, as the current of air which is necessary in the case of ether is not required, and simple and accurate determinations may be made without fitting up a complicated apparatus.

In conclusion, it may be mentioned that for medical application it still continues in considerable demand. Its use as a medium for spraying-on drugs in dermatological and surgical work is also becoming popular. Ethyl chloride containing 7% of phenol has been used successfully against vermin, and for killing mosquitoes and preventing bites.

At the commencement of the reading of the paper two glasses filled with ethyl chloride were exhibited on the table; at the end of the meeting the volume of the liquid was found to be practically unaltered, although the temperature was 65° F. (18° C.), which is considerably above its b. pt. (12.5° C.).

DISCUSSION.

The CHAIRMAN asked how the cost of ethyl chloride as a refrigerant compared with that of other materials.

Captain L. M. NASH asked whether oil or fat extracted by ethyl chloride was in a pure state or whether other substances were extracted. Was the solvent more in the nature of ether or petroleum spirit in regard to the extraction of matter other than fat?

The AUTHOR said there were other by-products as well, but they could be got rid of. He could not compare it with petroleum spirit because he had made no comparative tests.

Mr. S. B. TALLANTYRE said that in using ethyl chloride as an ethylating agent he believed it was usually dissolved in alcohol. Under such conditions, at 150° C. for instance, a fair amount of acidity was often developed, and this attacked iron

slightly. This appeared to show the unstability of ethyl chloride at temperatures above the normal.

Mr. HENNING said that he would ask Mr. Bishop to reply to the question as to the comparative cost of the ethyl chloride and the ammonia processes of refrigeration. There were probably 200 or 300 ethyl chloride machines at work, but they did not enable a very exhaustive statement to be made as to comparative cost. Ethyl chloride could be used instead of ether in connection with crystallisation.

Mr. C. BISHOP said that in his experience the capital cost of ethyl chloride plants was from 5 to 7½% more than that of carbon dioxide plants. These plants, however, had only been built for covering a certain small range, and they probably, owing to their range of size, cost more than either ammonia, carbon dioxide, or sulphur dioxide systems, but there were the advantages of simplicity, safety and automatic operation. The cost of running the various kinds of plant was practically the same.

Communication.

THE ESTIMATION OF ANILINE IN COMMERCIAL ANILINES.

BY WILLIAM JAMES SANDERSON AND WILLIAM JACOB JONES.

WHEN the aniline content of a commercial aniline is in question, methods of determination based on the reactions of aromatic amines are not permissible, since the toluidines are among the commonest impurities. Again, the boiling points of the substances present in commercial anilines are so near together that a method based on separation by fractional distillation is precluded. A method depending on the relation between the freezing point of the sample and its aniline content may, however, be applied, and such a method is described in this paper.

of the three phases, solid sodium hydroxide, saturated aqueous sodium hydroxide solution, and the aniline holding in solution a definite amount of water, comes to equilibrium, and the aniline layer, on separation from the other two phases, freezes at a definite temperature, which is dependent only on the aniline content of the sample under examination. For example, pure aniline, after having been subjected to this treatment, still holds in solution an amount of water which causes it to freeze at -6.30°C ., namely, 0.30° lower than the freezing point of pure, dry aniline.

Method.—To the aniline to be examined about 3% of its weight of water is added, and about 20% of solid sodium hydroxide. The mixture is allowed to stand with occasional shaking for 12 hours in a stoppered vessel. At the end of that time the aniline is separated and the freezing point determined by the usual Beckmann method. The thermometer used should be graduated to fifths or tenths of a degree and should be tested by means of melting ice (0°) and of freezing, pure, dry aniline (-6.00°), prepared as later described. The temperature will first fall and then suddenly rise. The highest temperature then attained is taken as the freezing-point, $t^{\circ}\text{C}$., of the aniline. If there be x parts by weight of aniline per 100 parts of organic matter in the aniline under examination, and if the chief impurity in the aniline is nitrobenzene, as, for example, in "aniline oils for blue," then $x = 113.3 + 2.11t$. If the chief impurities in the aniline are the toluidines, as, for example, in "aniline oils for red," $x = 110.7 + 1.70t$.

When the freezing point is below -10°C . it is advisable to mix a known weight or volume of the aniline with a suitable amount of purified aniline of known freezing point, so that the freezing point of the mixture comes above -10°C . Simple calculation then gives the percentage of aniline in the original aniline oil.

Purification of aniline.—The aniline used in the present work had been purified by repeated recrystallisation from itself, followed by dehydration over sodium hydroxide, and by final distillation. The freezing point of the aniline thus purified and dried was -6.00°C . on the international gas-thermometer scale. Ampola and Rimatori (*Gazzetta*, 1897, 27, A, 35), give -5.96°C .

Freezing points of dry, binary mixtures of aniline with :

Weight % of aniline	Benzene	Phenylhydroxylamine	Nitrosobenzene	<i>p</i> -Aminophenol	Nitrobenzene	<i>o</i> -Toluidine	<i>p</i> -Toluidine	<i>m</i> -Phenylenediamine	Nyldine
100	-6.00°	-6.00°	-6.00°	-6.00°	-6.00°	-6.00°	-6.00°	-6.00°	-6.00°
99	-7.18°	-6.47°	-6.58°	-6.58°	-6.53°	-6.66°	-6.65°	-6.60°	-7.00°
98	-8.00°	-6.94°	-7.16°	-7.16°	-7.03°	-7.18°	-7.25°	-7.18°	-7.75°
97	-8.70°	-7.41°	-7.74°	-7.74°	-7.50°	-7.75°	-7.85°	-7.75°	-8.48°
96	-9.30°	—	—	—	-7.97°	-8.33°	-8.45°	—	-9.00°
95	—	—	—	—	-8.43°	-8.95°	-9.05°	—	—
94	—	—	—	—	-8.85°	-9.53°	-9.63°	—	—
93	—	—	—	—	-9.27°	-10.11°	—	—	—

Owing to the solubility of water in aniline it is necessary, before determining the freezing point to bring the aniline to a definite state of dehydration or of hydration. In the case of impure anilines it is not permissible to effect complete dehydration by distillation, since part of the least volatile impurities would remain in the undistilled residue. It has, however, been found that the aniline may be brought to a fairly definite state of hydration by the following treatment. The aniline is just saturated with water, and about one-fifth of its weight of solid sodium hydroxide added to it. On being allowed to stand for twelve hours or longer, with occasional shaking, the resulting system consisting

Freezing points of aniline mixtures.—Mixtures containing pure dry aniline and the substances, carefully purified and dried, which are commonly associated with it in commercial anilines, were prepared, and their freezing points taken. The table, which shows the results obtained with binary mixtures, gives the percentage by weight of aniline present for various freezing points. Thus, a dry mixture consisting of 95% of aniline and 5% of nitrobenzene freezes at -8.43°C . It was found, as with pure aniline, that the freezing points of the mixtures, after they had been subjected to the treatment with water and sodium hydroxide already described, were in each case lowered by 0.3°C .

American Section.

Meeting held at Chemists' Club on November 21, 1919.

MR. C. E. SHOLES IN THE CHAIR.

INDUSTRIAL USES FOR THE SHARK AND PORPOISE.

BY DR. ALLEN ROGERS.

For several years the author has been interested in the utilisation of shark and porpoise skins for leather manufacture and has investigated the methods of handling this class of raw material. Through this work he became acquainted with Mr. Alfred Ehrenreich, President of the Ocean Leather Company, who has also spent many years in the study of this subject, and through whose efforts the establishment of an entirely new industry has been made possible.

During several recent visits to the Everglades of Florida and to Morehead City, North Carolina, the shark and porpoise have been studied in their native haunts, and the fact demonstrated beyond a doubt that it is possible to handle these animals in a commercial manner. As a result the Ocean Leather Company has now in operation at Morehead City a modern plant where the hides are removed and salted. In addition, at this plant the livers are rendered for their oil and the flesh converted into a high-grade fertiliser stock. At Sanabal Island, Florida, another factory is in the process of construction which will be a duplicate of the one at Morehead City.

The sharks are caught in nets of 8-inch mesh, 360 yards long and about twelve feet deep, made of heavy twine. As the boat picks up the buoy, one man standing in the stern pulls in the cork line, while another hauls up the lead. When the shark is brought up a rope is placed over the tail, or, in some cases, a hook is placed in the eye. If the fish is alive it is killed by a sharp blow with an axe, and then lifted on board by means of a block and fall. In an average haul from ten to twenty sharks are taken from each net.

On arriving at the dock the fish are unloaded, and the work of dressing at once started. The first operation is to remove the fins and tail. The fins are tacked on a rack and allowed to dry in the sun; they are used by the Chinese for making soup. The fish is then cut down the back, and a circular cut made over the neck and around the gills. The skin is finally removed in such a manner that only the hole of the pectoral fins and rectal opening remain in the pelt. The flayed skins are placed in salt for 24 hours, fleshed on the beam or machine, and then pickled with salt and sulphuric acid. The pickled skins are drained and placed in bundles for shipment.

The livers are thrown into barrels, where they are allowed to remain for several days to disintegrate, and then placed in steam-jacketed kettles and heated to boiling for about one hour.

From the kettles the oil is run into washing and settling tanks, where the gurry is separated from the oil. The oil is then drawn into a second tank, again washed, and finally run to a third tank, where it is stored until ready for shipment. Exposure to the sun and rain effects more or less bleaching.

The carcase of the shark may have possibilities as a food product, but at present is being used in the manufacture of fish scrap for fertiliser stock. The carcase is thrown into the hopper of a specially-designed mill, where the flesh and bones are ground to a fine pulp, which is dried in a rotary dryer. This grade of fish scrap contains on an average 15-17% of nitrogen expressed as ammonia.

The shark skins as they arrive at the tannery at Newark, N.J., are soaked in water to remove the salt and again fleshed. The skins for bag leather are limed and bated in the usual manner and tanned in bark. The tanned skins are then treated with strong hydrochloric acid by the Kohler process to remove the shagreen, and after washing and colouring are ready for the finishing process.

The skins to be used for shoe leather are not limed or bated, but are at once treated for the removal of the shagreen. This so-called shagreen is a very hard layer which covers the whole fish; it has the appearance of very coarse sand paper and is almost impossible to remove by mechanical means. The elimination of shagreen from the raw skins is a problem which until recently has remained unsolved. A process discovered by the author which consists in soaking the skins in a salt solution of 10° B. (sp. gr. 1.074) mixed with an equal volume of hydrochloric acid. The removal of the shagreen is accomplished in about two hours. By leaving skins in this solution for a week no damage occurs. The skins are neutralised in a salt solution of 10° B., to which soda ash is added from time to time. When free from acid the stock can be tanned by any of the methods now in vogue.

For several years the Bureau of Fisheries has endeavoured to interest the public in using shark meat for edible purposes with a certain amount of success. In fact, that species of shark known as dogfish is being canned in large quantities and sold under the name of grayfish. Some of the larger sharks are sold in certain markets as deep sea sword fish. In some places shark meat as such is offered to the trade and finds a ready market. When popular prejudice has been overcome it must be admitted that shark flesh is a fair rival of the halibut, better than the cod, and equal even to the much-prized sword fish.

The Ocean Leather Company alone expect to bring their catch to 1000 sharks per day, and with an estimated catch by other fishermen of 1000 daily we would have 2000 sharks averaging 100 lb., representing a supply of edible material to the amount of 75,000,000 lb. annually. If it should prove impossible to get this material to the market in a fresh condition, it is easily cured with salt and borax, and then compares favourably with any good grade of salted fish. It may also be smoked or kippered.

During numerous trips to North Carolina and to Florida a vast amount of data has been accumulated which is of value in determining yields and cost of production. Included in these data are many individual records, some of which

may be of interest as showing the size of fish and products secured. They are as follows:—

	Length.	Girth.	Weight.	Weight of liver.	Size of skins.
	ft. ins.	ft. ins.	lbs.	lbs.	sq. ft.
Tiger shark, male	7 8	3 0	128	24	9
female†	15 4	6 8	—	—	28
Cub shark, male	10 6	4 8	337	82	14
female	11 6	5 2	360	33	18
Sand shark, female	8 2	3 8	271	28	10
Hammerhead shark male	5 8	2 3	56	6	4

†Oil rendered, 21 gallons.

It will be seen that the ratio of liver to body varies in the different species, and also that in the same species there is a difference between male and female.

Although the porpoise are not so plentiful as sharks they deserve brief mention. Porpoise travel almost exclusively in schools, and are, therefore, usually caught in the purse seine. The method consists in surrounding the school and then landing them on the beach. These fish vary in size from 3 to 30 ft. Their skin carries a heavy layer of blubber, which is split off and rendered to obtain lubricating oil. On the face of the fish is an extra heavy blubber known as junk, which, when rendered separately, yields a more valuable oil than ordinary blubber oil. In the jaw cavity is a small amount of oil, about 1 oz. to a fish, known as jaw oil. This oil is carefully rendered and brings from \$30.00 to \$80.00 per gallon.

The flesh of the porpoise is very dark in colour and resembles liver in flavour. When cooked like beef it is very tender and delicious. The same prejudice is held for porpoise as for shark, so time must be allowed for the public to become educated to this food material. In the meantime the body is utilised for making fertilisers.

Liverpool Section.

DR. E. F. ARMSTRONG IN THE CHAIR.

THE MECHANISM OF THE ADDITION OF HYDROGEN TO UNSATURATED GLYCERIDES IN THE PRESENCE OF FINELY-DIVIDED NICKEL.

BY R. THOMAS, M.Sc., A.I.C.

PART I.

THE MECHANISM OF THE ADDITION OF HYDROGEN TO UNSATURATED GLYCERIDES.

The use of finely-divided reduced nickel as a catalyst in chemical reactions involving the addition of hydrogen to unsaturated organic compounds has of recent years been the subject of several technical applications. Although its suitability for such reactions was first established by Sabatier and Senderens as far back as 1897, and numerous investigations dealing with it have since been published by them and other authors, none of these, as far as I am aware, deal very exhaustively

with the subject from a dynamical standpoint, and of course, from the manufacturing point of view, the velocity of the reaction is a most important consideration. These earlier discoveries of Sabatier and Senderens have received their widest application in "fat hardening," i.e., the conversion of liquid oils or fatty acids into more valuable solid products.

The results embodied in this communication were obtained by the author in 1914 during the course of some technical investigations undertaken on the subject.

The unsaturated glyceride chosen as a starting point for these experiments was olive oil, as it was the nearest approach to a chemical entity among either vegetable or animal oils. In order to avoid the possibility of introducing traces of catalyst poisons it was considered better to use the naturally occurring product, after purification, than to synthesise olein, $C_3H_5(OC_{18}H_{33}O)_3$, as synthesis involves the use of materials which are well known to be "poisons" even when occurring in very minute quantities.

Purification of the oil.

Caustic soda solution, in amount a little in excess of that required for the neutralisation of the free fatty acids present, was added to the olive oil. The liquid was separated from the soap which was thrown out, washed several times with water, and dried *in vacuo*. Analysis by the method described by Lewkowitch* showed that the liquid glyceride was composed of 93% of olein, $C_3H_5(OC_{18}H_{33}O)_3$, and 7% of linolin, $C_3H_5(OC_{18}H_{31}O)_3$. According to Ubbelohde and Goldschmidt† the percentage of linolin varies from 7% to 10% of the liquid glycerides of various samples of olive oil.

Preparation of the catalyst.

The finely-divided nickel used as catalyst in these experiments was obtained by reducing precipitated nickel hydroxide in a current of pure hydrogen at 360° C., with the usual precautions necessary to obtain a product of high catalytic activity.‡ Enough catalyst was prepared to last through the whole series of experiments, care being taken that its "activity" remained unimpaired by keeping it out of contact with air.

The hydrogen employed both for reducing the catalyst and carrying out the hydrogenation of the unsaturated glycerides was obtained by electrolysis, and was of a very high degree of purity.

Theoretical considerations.

The presence of 7% of linolin (iodine value 173) mixed with olein (iodine value 85) makes it necessary in any accurate investigation of velocity of hydrogenation to find mathematical expressions for the transformation of both glycerides, as the former is responsible for 13–14% of the total hydrogen absorption of olive oil. The presence of two sets of double bonds in linolin gives rise to three distinct possibilities, either a direct saturation to stearin or the formation of olein (or its isomer) as an intermediate product. From several considerations I am inclined to think that the saturation of a compound containing two sets of double bonds may follow one or all of the above alternative courses according to conditions, the determining factors being (a) the nature of the catalyst, (b) its amount, and (c) its activity, together with (d) the temperature at which the reaction is carried

* Lewkowitch, "Chemical Technology and Analysis of Oils, Fats, and Waxes," Vol. 1, p. 560.

† "Handbuch der Oele und Fette," Vol. 3, p. 524.

‡ Sabatier, "La Catalyse en Chimie Organique," pp. 54–55.

out. It is quite conceivable, for instance, that a large amount of catalyst and high temperature would favour direct transformation of linolin to stearin. What actually happens in normal practice is that the three reactions:—Linolin \rightarrow stearin; linolin \rightarrow olein \rightarrow stearin; and linolin \rightarrow iso-olein \rightarrow stearin, occur simultaneously, the comparative extent depending on the above-mentioned conditions. Ubbelohde and Svanoe³ conclude that the clupanodonic acid in whale oil adds on four hydrogen atoms simultaneously, forming a linolic acid without the intermediate formation of linolenic acid. In the case of cottonseed oil, however, the same authors state that the linolic acid is first transformed into iso-oleic acid. It is not intended in the present communication to enter into a fuller discussion of this phase of the subject, as it does not materially affect the immediate object in view, namely, to show as a basis for the rest of this paper, that the addition of hydrogen at constant pressure to olive oil is a unimolecular reaction. The following equations were deduced on this assumption, and the agreement between the observed values of the

where k_2 is the velocity constant of the reaction linolin + hydrogen \rightarrow stearin.

From (i) we have in the usual way $k_1 = \frac{1}{t} \log \frac{a}{a-y}$ or

$$y = a(1 - e^{-k_1 t}) \dots \dots (iii.)$$

Similarly from (ii)

$$z = b(1 - e^{-k_2 t}) \dots \dots (iv.)$$

If x be the total hydrogen absorbed at the time t , then

$$x = y + z = a(1 - e^{-k_1 t}) + b(1 - e^{-k_2 t})$$

$$\text{or } ae^{-k_1 t} + be^{-k_2 t} = (a+b) - x \dots \dots (v.)$$

This expression enables us to calculate k_1 and k_2 .

For at intervals of time t_1 and t_2 we have:—

$$ae^{-k_1 t_1} + be^{-k_2 t_1} = (a+b) - x_{t_1}$$

$$ae^{-k_1 t_2} + be^{-k_2 t_2} = (a+b) - x_{t_2} \dots (vi.)$$

Putting $e^{-k_1 t_1} = M \dots (vi.)$ and $e^{-k_2 t_1} = N \dots (vii.)$

and choosing t_1 and t_2 so that $t_2 = 2t_1$ we obtain

$$aM + bN = (a+b) - x_{t_1} \dots \dots (viii.)$$

$$aM^2 + bN^2 = (a+b) - x_{t_2} \dots \dots (ix.)$$

Fig. 1.

hydrogen absorption and those calculated from the equations justifies this assumption:—

If a = amount of hydrogen necessary to saturate completely the olein in olive oil.

y = amount of hydrogen absorbed by the olein in time t .

b = amount of hydrogen necessary to saturate completely the linolin in olive oil.

z = amount of hydrogen absorbed by the linolin in time t .

then $\frac{dy}{dt} = k_1(a-y) \dots \dots (i.)$

where k_1 is the velocity constant of the reaction olein + hydrogen \rightarrow stearin.

$$\frac{dz}{dt} = k_2(b-z) \dots \dots (ii.)$$

a and b are known from the iodine value of the oil and the relative proportions of olein and linolin present. x_{t_1} and x_{t_2} are determined experimentally.

Solving the equations (viii) and (ix) in the usual way we get M and N , and hence k_1 and k_2 from (vi) and (vii).

In order to test the validity of the above expression k_1 and k_2 are calculated for values of, say, $t_1 = 10$ minutes and $t_2 = 20$ minutes. With the values of k_1 and k_2 so obtained, x_t is calculated for the remaining values of t , and the values of x compared with those determined experimentally. Figure 1 shows the apparatus employed for the determination of the rate of absorption of hydrogen by olive oil.

Into A, which is conveniently made out of a 100 c.c. pipette, 10 grms. of oil and the requisite amount of nickel are introduced. B is a piece of

rubber tubing connecting to C, which contains anhydrous calcium chloride to dry the hydrogen. D contains glass wool to stop any liquid water being drawn into C during the evacuation of E. The latter is of about 1000 c.c. capacity and graduated. It is connected, as shown, to a hydrogen reservoir, and also to F containing water. The apparatus is evacuated and filled with hydrogen, these two operations being repeated several times to ensure the entire absence of air. When the apparatus is finally full of hydrogen at atmospheric pressure, A is shaken at a constant rate (400 double strokes per minute) by an electrical shaking arrangement in a bath, O, containing oil or other suitable material and maintained at a constant temperature. The absorption at atmospheric pressure after definite intervals of time is observed by reading the level of the water in E in the usual way.

The arrangement described enables the rate of absorption of hydrogen to be measured with considerable accuracy. Several repetitions of an experiment yielded results in which the maximum difference in the absorption in a given time was only 2%.

Experimental results.

The iodine value of the purified olive oil used in these experiments was 86, corresponding to a hydrogen absorption at 20° C. and 760 mm. of 815 c.c. The values of a and b in equations viii and ix are therefore 708 and 107. Two typical experiments carried out at 180° C. using 1.0% of nickel as catalyst (calculated on the oil) gave the following results:—

I.

Time (mins.).	x (observed).	x (calc.).	k_1 (olein).	k_2 (linolin).
	c.c.	c.c.		
5	67	64	—	—
10	118	118	—	—
20	203	203	0.00880	0.068
30	265	269	—	—
60	428	416	—	—
90	539	519	—	—

II.

Time (mins.).	x (observed).	x (calc.).	k_1 (olein).	k_2 (linolin).
	c.c.	c.c.		
5	66	65	—	—
10	120	120	—	—
20	204	204	0.00884	0.066
30	270	274	—	—
60	433	423	—	—
90	646	530	—	—

The observed and calculated values of x at 10 mins. and 20 mins. are, of course, identical, as the observed values in these two cases were employed for calculating k_1 and k_2 as already described. The agreement between these two sets of values for other values of t is very satisfactory.

With the same concentration of nickel at 150° C. and 120° C. the values obtained were:—

Temp. = 150° C.

Time (mins.).	x (observed).	x (calc.).	k_1 (olein).	k_2 (linolin).

30	131	130	—	—
60	226	225	—	—
90	294	299	—	—

The results detailed above show that the addition of hydrogen at constant pressure to a mixed unsaturated glyceride such as olive oil in the presence of nickel as catalyst is a reaction of the first order. Fokin* showed that the reaction between oleic acid and hydrogen is a unimolecular re-

action, according to the equation $k = \frac{1}{t} \log \frac{a}{a-x}$

PART II.

THE FUNCTION OF THE CATALYST.

Sabatier† considers the action of the catalyst to be due to the alternate formation and decomposition of an unstable nickel hydride. Variations in the activity of the catalyst are ascribed to its power of forming different hydrides, the higher hydrides being more active than the lower. No physical or chemical evidence exists, however, which shows the possibility of the formation of a compound of nickel and hydrogen. On this theory, moreover, it would be difficult to explain either the influence of small amounts of catalyst poisons or of catalyst promoters. Armstrong and Hilditch‡ compare the action of nickel in fat hardening to that of an enzyme in the hydrolysis of glucosides.

A good deal of light can be obtained on the mechanism of the catalytic action of nickel in fat hardening from a consideration of (i) the influence of the pressure of hydrogen on the velocity of hydrogenation and (ii) the temperature coefficient of the reaction.

Influence of pressure.

This was determined by means of a simple modification of the apparatus described in figure 1, as shown in figure 2.

Fig. 2.

The apparatus is filled in the usual way (T being left open) with hydrogen at the required pressure from the hydrogen cylinder (the highest pressure which could be safely employed with the glass apparatus was 2 atmospheres). The pressure is indicated on the closed manometers, R and S, as

* Fokin, J. Russ. Phys.-Chem. Soc., 1908, 40, 276.

† "Die Hydrierung durch Katalyse." "La Catalyse en Chimie Organique," p. 254.

‡ Proc. Roy. Soc., 1919, A, 96, 137; this J., 1919, 780A.

well as on a pressure gauge attached to the hydrogen cylinder. When the apparatus has been finally filled at the pressure indicated on R and S the pressure tap, T, is closed, leaving only the reservoir, F, in communication with the cylinder. During the progress of the reaction the water rises in E and falls in F. The pressure in E at any time as registered by the manometer, R, is the pressure in F (registered on S and kept constant by communication with the cylinder) minus the difference in level in the water in E and F. If the diameters of E and F are about 2½—3 inches, then the final pressure at the end of the absorption is only about 5 or 6 inches of water less than at the start. This is a very small variation on a pressure of, say, 2 atmospheres, being only about 0.75%. The results obtained at 180° C. and pressures of 1.9, 1.0, and 0.8 atmospheres were as follows:—

Pressure = 1.9 atmospheres.

Time (mins.).	x (observed).	x (calc.).	k_1 (olein).
5	139	139	—
10	223	223	0.0254
20	345	350	—
40	523	541	—
60	626	645	—

Pressure = 1 atmosphere.

Time (mins.).	x (observed).	x (calc.).	k_1 (olein).
10	106	104	—
20	182	183	—
40	306	308	0.0095
60	394	402	—
80	468	474	—

Pressure = 0.8 atmosphere.

Time (mins.).	x (observed).	x (calc.).	k_1 (olein).
10	93	94	—
20	160	150	—
40	257	248	0.0070
60	320	331	—
80	384	400	—

The values of x in the foregoing table have been corrected for pressure and represent the absorption at 20° C. and 760 mm. k_1 is the velocity constant for olein, calculated from equations viii and ix, the calculated values for x being derived from the same expressions. (In these remarks on the influence of pressure and likewise in the forthcoming consideration of the temperature coefficient, attention is confined to olein. k_2 (linolin) was calculated in each case, but naturally its value is not of the same degree of accuracy as that of k_1 (olein) on account of the preponderance of the latter constituent).

The next table shows the relation between the pressure of hydrogen and the velocity constant k_1 .

Pressure (atm.).	k_1 .	$k_1 \div p^{1.5}$
0.8	0.0070	0.0097
1.0	0.0095	0.0095
1.9	0.0254	0.0096

Thus the velocity constant of the reaction is proportional to $p^{1.5}$ where p is the pressure under which the hydrogen reacts. That this is in accordance with the requirements of the law of mass action the following consideration will show:—

The hydrogenation is represented by the equation

For the velocity of the reaction we have therefore:—

$$\frac{dx}{dt} = k C_{\text{olein}} \times (\text{C}_{\text{H}_2})^3$$

i.e., it is proportional to the third power of the concentration of the hydrogen actually at the seat of the reaction, i.e., in the oil or catalyst. To evaluate this we must know the relation existing between it and the pressure of hydrogen in the rest of the apparatus.

Sieverts, in a series of papers in the *Zeitschrift für physikalische Chemie* and *Zeitschrift für Elektrochemie*, has made a very exhaustive investigation of the solubility of hydrogen in various metals. He gives figures* for the absorption of hydrogen by nickel for temperatures from 200° C. to 1600° C. and pressures up to 1.5 atmospheres. At constant temperature the solubility of hydrogen in nickel is proportional to the square root of the pressure. The hydrogen absorbed is thus probably in an atomic condition for in the equilibrium $\text{H}_2 \rightleftharpoons 2\text{H}$, $\text{C}_{\text{H}} = K\sqrt{\text{C}_{\text{H}_2}}$. For C_{H_2} in the expression for the rate of hydrogenation we can therefore substitute $\sqrt{P_{\text{H}_2}}$ where P is the pressure of the hydrogen, and we obtain:—

$$\frac{dx}{dt} = k C_{\text{olein}} \times (\sqrt{P_{\text{H}_2}})^3$$

in other words, the velocity is proportional to $P^{1.5}$, which is in agreement with our experimental results.

The first function of the catalyst is therefore to absorb the hydrogen, the absorbed or occluded gas being in a highly "active" condition, in all probability in the atomic condition. The absorption occurs of course through the medium of the oil, in which hydrogen has a solubility of 5.5% by volume, at 180° C.†

Having thus seen how the hydrogen molecules become "active" it will now be of interest to consider the manner in which the olein molecule—the other participant in the reaction—becomes reactive. A consideration of the temperature-coefficient of the reaction will help to elucidate this point.

The temperature-coefficient of the reaction velocity (k_1).

Arrhenius explains the accelerating effect of temperature on the velocity of a reaction by assuming a mass action equilibrium between "active" and "inactive" molecules, an increase of temperature favouring the formation of a greater number of "active molecules."‡ This conception is criticised by Lewis and Lambell,§ who put forward arguments in favour of assuming the existence of physically active molecules rather than chemically active molecules in mass action equilibrium as suggested by Arrhenius. On either of these views, and on any reasonable theory of catalysis, it is clear that in the case of a catalysed reaction the temperature coefficient must vary to a certain extent with the concentration of the catalyst. The greater the concentration of the catalyst, the smaller should the temperature coefficient be. As long as the number of "active" molecules is small the lowering effect of catalyst

* Z. physik. Chem., 1911, 591.

† Ubbelohde and Svanoe, Z. angew. Chem., 1919, 32, 257; see this J., 1919, 870A.

‡ Z. physikal. Chem., 1889, 4, 226.

§ Chem. Soc. Trans., 1915, 197, 235.

concentration on the temperature coefficient will be a slight one, but if for any reason, such as the presence of a very large amount of catalyst, the number of "active" molecules is large compared with the number of "inactive" ones, then the accelerating effect of temperature is much smaller.

As shown in the first part of this communication, the values of k_1 (the velocity constant for olein) using 1% of nickel at 120°, 150°, and 180° were 0.00355, 0.00587, and 0.00884 respectively, which are in the ratio 1:1.66:2.5. Experiments were conducted at these temperatures using 0.5% of nickel, the velocity contents being 0.00180, 0.00305, and 0.00490 respectively, which are in the ratio 1:1.7:2.7; with 0.2% of nickel the corresponding ratios were 1:1.7:2.8. These results are summarised in the following table:—

Conc. of Ni.	$\frac{k_{150^\circ}}{k_{120^\circ}}$	$\frac{k_{180^\circ}}{k_{120^\circ}}$
1.0	1.66	2.5
0.5	1.70	2.7
0.2	1.70	2.8

Thus the temperature coefficient is slightly diminished as the concentration of the catalyst increases. This diminution is, however, only small even when the catalyst concentration is increased five-fold (from 0.2 to 1.0), and thus the total number of "active" molecules present is small in comparison with the total number of molecules.

A glance at the above figures will show that the temperature coefficient of the hydrogenation of an unsaturated glyceride like olein is a small one, an increase of temperature of 60° C. only increasing the value of the velocity constant 2.8 times, and indeed the real value of the temperature coefficient is even smaller than would at first sight appear, since at the higher temperature nickel absorbs more hydrogen, and as the velocity is proportional to the third power of the concentration of the absorbed or "active" hydrogen, an appreciable fraction of the increase in value of the velocity constant is due to this factor. In order to arrive at the real temperature coefficient of the reaction, it becomes necessary therefore to allow for this increased hydrogen concentration. For the whole range of temperatures investigated by Sieverts (*loc. cit.*) up to the melting point of nickel I find that the influence of temperature on the solubility of hydrogen in nickel can be represented with considerable accuracy by the expression:—

$$\frac{1}{m} \frac{dm}{d\theta} = \alpha - \beta \theta \quad \dots \dots (x)$$

where m is the amount of hydrogen dissolved, the temperature in degrees centigrade and α and β are constants. This equation on integration gives:—

$$\log \frac{m_2}{m_1} = \alpha (\theta_2 - \theta_1) - \frac{\beta}{2} (\theta_2^2 - \theta_1^2) \dots \dots (xi.)$$

from which it is calculated that an increase of temperature of 60° in the neighbourhood of 200° C. increases the solubility of hydrogen in nickel 1.14 to 1.15 times.

It is interesting to note in this connection that the solubility of hydrogen in oil also increases with temperature. Thus at 180° C. it is about 1.3 times as great as the solubility at 120° C.,* so that the relative increase in the solubility of hydrogen in nickel is equal to the square root of the relative increase of the solubility in oil ($\sqrt{1.3} = 1.14$), which is additional evidence in favour of the view put

forward in this paper as to the mechanism of the reaction. The increase in the value of k , therefore, on account of the increased solubility of hydrogen in nickel with temperature is 1.5 times ($= 1.15^2$) for an increase of 60° C. The true value of $k_{180^\circ}/k_{120^\circ}$ is therefore only 1.9 ($2.8 \div 1.5$), while $k_{150^\circ}/k_{120^\circ}$ is practically 1.45. These figures give a value for $(k_{t+10})/k_t$ of about 1.13. A low temperature coefficient of this order of magnitude is generally associated either with diffusion catalysis or with a photochemical reaction. On account of the very vigorous shaking of the oil with the catalyst the former possibility is excluded, and it would appear therefore that the reaction is of the nature of a photochemical reaction, due of course in this case to infra-red radiation. For the photochemical decomposition of SO_3 to SO_2 and O_2 under the influence of ultra-violet rays, Coehn and Bacher* found that for the temperature range 50°—160° C. the value of k_{t+10}/k_t was 1.2, which is of the same order as the value 1.13 found above.

The photochemical equivalent law as developed by Einstein† postulates that a photochemical reaction takes place by the absorption of quanta of radiant energy, one molecule being decomposed by one quantum E equal to $h\nu$, where h is Planck's universal constant and ν is the vibration frequency of the radiant energy absorbed. Bodenstein‡ applied this law to several photochemical reactions, and found that a small number (one to four) of quanta per molecule are absorbed to bring about the reaction (in one case the number was as high as nine). In recent years the application of Einstein's photochemical law has been extended to include radiation carried by long waves (infra-red), thermal reactions being regarded as occurring through the absorption of infra-red radiation, the energy transfer occurring in terms of quanta (in this connection see Trautz, Z. wiss. Phot., 1906, 4, 160; Richardson, Phil. Mag., March, 1914).

Lewis§ has carried out an exhaustive investigation of catalysis in homogeneous systems, and was the first to suggest that "Catalysis is essentially a radiation phenomenon."†† a suggestion which is supported by a considerable amount of experimental evidence published in a series of papers by Lewis and others during the years 1914—1918. For the effect of temperature on the velocity constant of a reaction, Marcelin** has deduced thermodynamically the expression $\frac{d \log k}{dt} = \frac{E}{RT^2}$, where E is

the energy absorbed by the molecule in excess of the average energy of all the molecules before it becomes active. He calls E the "critical energy," a more suitable term being "critical increment," ‡‡ as suggested by Lewis and Lamble (*loc. cit.*), who utilise this expression for the hydrolysis of methyl acetate, the inversion of sucrose, etc., applying at the same time the radiation theory of catalysis.

If we apply Marcelin's equation (above) to the hydrogenation of olein we obtain by integration:—

$$\log \frac{k_{180^\circ}}{k_{120^\circ}} = \frac{E}{R} \left(\frac{1}{393} - \frac{1}{453} \right) = \log 1.9;$$

hence E is equal to 3820 calories per grm.-mol. or 16.2×10^{11} ergs. If the reaction is photochemical, occurring through the absorption of one quantum

†† Loc. cit., 1914, 2336.

‡‡ Rice gives a mathematical conception of this in the equation $\frac{d \log k}{dt} = \frac{V_c - V_m + \frac{1}{2} RT}{RT^2}$

where V_c denotes the critical value of the internal energy of a number of molecules and V_m the mean potential energy of the molecules.

* Ubbelohde and Svanoe. Z. angew. Chem., 1919, 32, 257, 280; see this J., 1919, 870A.

($=h\nu$) of radiant energy per molecule, this figure (16.2×10^{11} ergs) should be equal to $Nh\nu$, where N is the number of molecules per gram. molecule (6.15×10^{23}), and h (Planck's constant) is equal to 7×10^{-27} . Substances containing CH_2 and CH groups show a characteristic absorption band at about 6.86μ . If, therefore, we take the value 7μ for λ , and hence

$$\frac{3 \times 10^{10}}{7 \times 10^{-4}} \text{ for } \nu \left(= \frac{\text{velocity of light}}{\text{wave length}} \right)$$

we get for $Nh\nu$ the value 1.81×10^{11} ergs. Thus E and $Nh\nu$ are in fair agreement.

Let us now consider the radiation emitted by the catalyst. Reduced nickel is a "full radiator," and we may therefore apply to it Wien's displacement law, i.e.:—

$$\lambda_{\text{max}}. T = b \text{ and } E\lambda_{\text{max}} = aT^5$$

where λ_{max} is the length of the particular waves which carry most of the radiant energy and $E\lambda_{\text{max}}$ the energy carried by the waves of length λ_{max} . Taking Lummer and Pringsheim's value for b , i.e., 2940×10^{-4} , it is seen that at the temperatures of these experiments λ_{max} is in the neighbourhood of 7μ . Thus at 150°C . we have:—

$$\lambda_{\text{max}} \times (273 + 150) = 2940 \times 10^{-4} \\ \text{or } \lambda_{\text{max}} = 7\mu.$$

It would appear therefore that the unsaturated glyceride becomes reactive by the absorption of one quantum (per molecule) of the radiant energy emitted by the catalyst, the vibration frequency being that corresponding to the maximum radiation. Or again, if this is the case, then since the maximum energy radiated is proportional to the fifth power of the absolute temperature ($E\lambda_{\text{max}} = aT^5$), then we should expect:—

$$\frac{k_{180}^\circ}{k_{120}^\circ} = \left(\frac{273 + 180}{273 + 120} \right)^5 = 2.0$$

the figure found by experiment being 1.9.

The cause of the reactivity of the hydrogen has already been explained when dealing with the effect of pressure on the velocity of the reaction, as due to absorption by the catalyst, accompanied by a splitting into atoms. By extending Lewis's radiation hypothesis of homogeneous catalysis to catalysis in a heterogeneous system as shown above, the reactivity of the olein molecules can be explained. We thus have all the conditions necessary for a reaction to occur between the unsaturated glyceride and the hydrogen, both being in an active condition through the instrumentality of the catalyst.

PART III.

THE INFLUENCE OF FOREIGN GASES ON THE CATALYST (CATALYST POISONING) AND ON THE VELOCITY OF HYDROGENATION.

It has already been shown that the first function of the catalyst is to absorb hydrogen, and that the power of absorption is proportional to \sqrt{p} where p is the hydrogen pressure. Further, it was proved that the velocity of hydrogenation of olein is proportional to the third power of the "active" hydrogen in accordance with the equation:—

and therefore proportional to $p^{1.5}$. On this account alone the presence of gaseous impurity will have an appreciable retarding effect on the rate of a heterogeneous reaction of this type, since there is an accumulation of the impurity as the hydrogen is

absorbed, there being little, if any, diffusion of the gaseous impurity against the current of absorbed hydrogen. In order to prevent any possibility of backward diffusion a "trap" was inserted in the apparatus described in figure 1, between the calcium chloride tube and the reaction vessel. The "trap" consisted of a "bubbling tube" containing any suitable liquid through which the hydrogen passed on its way to the oil. The apparatus was filled with hydrogen containing a certain percentage of the gaseous impurity under investigation, and from the dimensions of the entrapped space the percentage of impurity present at any stage of the absorption could be accurately estimated.

If the volume of the "entrapped" space is V and the hydrogen contains n parts per unit volume of the gaseous impurity under consideration, then $V - nv$ is the volume of pure hydrogen originally present in this space. Put $V - nv = V_0$, then when x c.c. of hydrogen have been absorbed by the oil, the volume of pure hydrogen in the entrapped space is $V_0 - nx$. The partial pressure of the hydrogen at any time, t , in which x c.c. has been absorbed is therefore proportional to this quantity.

$$Px = \frac{1}{V} (V_0 - nx) \\ \text{when the total gas pressure is 1 atmosphere.} \\ = \frac{n}{V} (V_0/n - x) \\ = \phi (c - x) \text{ where } V_0/n = c, \text{ a constant for a given} \\ \text{initial fraction of impurity.} \\ \text{and } n/V = \phi = \text{constant.}$$

It was shown earlier that the addition of hydrogen at constant pressure to an unsaturated glyceride follows the unimolecular law, and therefore for olein we have:

$$\frac{dx}{dt} = kp^{1.5} (a - x)$$

p being the pressure of hydrogen. With the pure gas at constant pressure, this of course resolves itself into $k(a - x)$.

For hydrogen containing a gaseous impurity, therefore, if this impurity has no further action than lowering the partial pressure of the hydrogen the reaction velocity is represented by

$$\frac{dx}{dt} = k \phi (a - x) (c - x)^{1.5} \\ = k_1 (a - x) (c - x)^{1.5} \quad \dots \quad (\text{xii.})$$

where ϕ and c have the significance mentioned above. Thus we have

$$\int_0^x \frac{dx}{(a - x) (c - x)^{1.5}} = k_1 \int_0^t dt \quad (\text{xiii.})$$

In order to integrate this expression it is transformed thus:

$$\int_0^x \frac{dx}{(a - x) (c - x) \sqrt{c - x}} = k_1 \int_0^t dt$$

Substituting y for $\sqrt{c - x}$, enumerating the other factors containing x in terms of y , and resolving into partial fractions, we obtain

$$-\frac{2}{a - c} \left[\int \frac{dy}{y^2} - \int \frac{dy}{y^2 - (c - a)} \right] = k_1 \int dt$$

Integrating and re-substituting $\sqrt{c - x}$, etc., we have

$$\frac{2}{c - a} \left[-\frac{1}{\sqrt{c - x}} - \frac{1}{2\sqrt{c - a}} \cdot \log \frac{\sqrt{c - x} - \sqrt{c - a}}{\sqrt{c - x} + \sqrt{c - a}} \right]_0^x = k_1 \left[t \right]_0^t$$

and therefore

$$k_1 = \frac{1}{t} \cdot \frac{2}{c-a} \cdot \left[\frac{1}{\sqrt{c}} \frac{1}{\sqrt{c-x}} \frac{1}{2\sqrt{c-a}} \right. \\ \left. \log \frac{(\sqrt{c-x} - \sqrt{c-a})(\sqrt{c} + \sqrt{c-a})}{(\sqrt{c-x} + \sqrt{c-a})(\sqrt{c} - \sqrt{c-a})} \right] \dots (\text{xiv.})$$

This expression holds good, of course, only for pure tri-olein. When another unsaturated glyceride is present as well, such as linolin in olive oil, allowance has to be made for this. The velocity expressions for olive oil using pure hydrogen, were deduced in Part I. (equations viii. and ix.), the experimental results agreeing well with the theoretical deductions. The deduction of a similar perfectly valid expression for the transformation of olive oil in the presence of hydrogen containing foreign gases would become very complicated, while, on the other hand, treating olive oil as if the liquid glyceride consisted only of olein gives rise to a considerable error, as will be seen from the following table for olive oil and pure hydrogen:

Time (mins.).	x (absorption).	$k = \frac{1}{t} \log \frac{a}{a-x}$
10	92	0.0119
20	155	0.0105
40	254	0.0066
60	347	0.0044
80	419	0.0092

Thus k is by no means constant. The drop in the value of k is most marked in the initial stages of the reaction, as would be expected from the considerably greater velocity of transformation of linolin than of olein (see Part I.). When the absorption has reached 150 c.c. practically all the linolin has disappeared, and the fall in value of k becomes considerably smaller and more gradual. By confining our calculations therefore to absorptions above this figure, equation (xiv.) will express to a first approximation the course of the reaction with olive oil and hydrogen containing a foreign gas which acts only as a diluent. Experiments were conducted with hydrogen containing several different foreign gases. We will confine our attention to three of them, which are typical of the rest namely:—

(a) *Nitrogen*, as typical of gases which undergo no chemical action with or under the influence of either the catalyst, glyceride, or hydrogen.

(b) *Carbon monoxide*, as typical of gases which undergo a transformation with hydrogen in the presence of the catalyst.

(c) *Hydrogen sulphide* as typical of gases which unite with the catalyst.

Influence of nitrogen.

The nitrogen used was passed several times over heated copper to ensure the complete absence of oxygen, and then mixed with the hydrogen in the required proportion. The rate of absorption by olive oil was compared with that of pure hydrogen under the same conditions (1% of nickel and 180° C.). The volume of the "trapped" space was 95 c.c., i.e., as the absorption occurs the nitrogen accumulates in this space. Using hydrogen containing 3% of nitrogen, the absorption proceeded as shown in the next table, compared with pure hydrogen.

For hydrogen containing 3% nitrogen the value of c in equations (xii.), (xiii.), and (xiv.) is 3072, since $d=0.03$, $V=95$, and $V_0=92.15$. The value of a in equation (xiii.) is, of course, the total hydrogen absorption corresponding to the iodine value of the

oil (=815). On substituting the values of x found above in equation (xiv.) it was evident that the

Concentration of nickel=1.0%.

Pure hydrogen.		Hydrogen containing 3% of nitrogen, x =absorption (c.c.).		
Time (mins.).	Absorption (c.c.).	Time (mins.).	x First expt.	x Second expt.
5	50	5	48	49
10	92	10	89	87
20	155	20	147	138
40	254	40	217	205
60	347	60	259	246
80	419	80	296	280

absorption fell much more rapidly than is represented in that equation. Thus, the relative value of k dropped from 60 to 40 in the period from 20 to 80 minutes, which is a much greater fall for the same range of absorption than the error introduced by regarding olive oil as olein, and which amounts for the range of absorption under consideration to a fall of about 10%. It has been tacitly assumed by many investigators on catalysis that nitrogen is merely a diluent, but it is quite clear from the above results that it has some further action than mere dilution; (fig. 3 shows this quite clearly). All the nitrogen could be recovered at the end of the experiment, and no trace of ammonia could be detected, showing that there is no chemical action of nitrogen either with the catalyst or with the hydrogen. Its action must therefore be physical, probably diminishing the power of the catalyst for occluding hydrogen* (over and above, of course, the obvious diminution of the amount of hydrogen occluded owing to a diminution in the partial pressure of the gas). The activity of the catalyst will therefore diminish as the nitrogen accumulates, i.e., as x increases. In order to follow the course of the reaction therefore, a term must be introduced into equation (xii.) to denote the falling activity of the catalyst, i.e.,

$$\frac{dx}{dt} = k(f)b.(a-x)(c-x)^{1.5}$$

Where $(f)b$ is a function of the activity of the catalyst, this function is of the form $b-x$, since the activity diminishes as the nitrogen increases and nitrogen increases as x increases. We have therefore:—

$$\frac{dx}{dt} = k(a-x)(b-x)(c-x)^{1.5}$$

$$\text{or } \int_0^x \frac{dx}{(a-x)(b-x)(c-x)\sqrt{c-x}} = k \int_0^t dt$$

Integrating the expression in the same manner as equation (xiii.) we obtain:—

$$k = \frac{2}{(a-b)(c-b)(c-a)} \frac{1}{t} \left[\frac{b-a}{\sqrt{c}} - \frac{b-a}{\sqrt{c-x}} + \frac{c-b}{2\sqrt{c-a}} \right. \\ \left. \log \frac{(\sqrt{c-x} - \sqrt{c-a})(\sqrt{c} + \sqrt{c-a})}{(\sqrt{c-x} + \sqrt{c-a})(\sqrt{c} - \sqrt{c-a})} + \frac{a-c}{2\sqrt{c-b}} \right. \\ \left. \log \frac{(\sqrt{c-x} - \sqrt{c-b})(\sqrt{c} + \sqrt{c-b})}{(\sqrt{c-x} + \sqrt{c-b})(\sqrt{c} - \sqrt{c-b})} \right] \dots \dots (\text{xv.})$$

* Bancroft (Amer. Electrochem. Soc., Oct., 1917) comes to an analogous conclusion in an article on "Poisoning of catalytic agents." He refers to the synthetic ammonia process (Haber), the decomposition of hydrogen peroxide in presence of platinum, the Sabatier hydrogenation process, etc., and concludes that actions of "poisons (solid, liquid, or gaseous) on catalysts is due to the occurrence of an adsorption process, which interferes with the normal adsorption of the reagents."

The value of b is thus found to be 500, and for 3% of nitrogen we have the following results:—

Time (mins.).	x (absorption in c.c.).	$\frac{1}{2}k(a-b)(c-b)(c-a)$ (from equation xv.).
20	147	0.115
40	217	0.104
80	296	0.104

Similarly, with 0.5% of nickel the rate of absorption was:—

Conc. of catalyst = 0.5%.

Pure hydrogen.		Hydrogen containing 3% of nitrogen.		$\frac{1}{2}k(a-b)(c-b)(c-a)$ (from equation xv.).
Time (mins.).	Absorption (c.c.).	Time (mins.).	Absorption (c.c.).	
20	89	20	74	—
40	142	40	121	—
50	162	50	136	0.046
100	263	100	197	0.041
200	411	225	319	0.043

The value of b was thus found to be independent of the concentration of nickel, but varies with the nature of the gas and its concentration. This is the result that one would expect from the manner in which b was deduced. It was suggested that some nitrogen was adsorbed or occluded on the surface of the catalyst, and the amount so occluded would, *ceteris paribus*, be proportional to the surface, which, in its turn, is proportional to the concentration of the catalyst. When the catalyst concentration is reduced therefore the amount of occluded nitrogen is reduced in the same proportion.

Similarly, a and b are, of course, independent of the catalyst concentration, while c varies with the concentration of nitrogen in a manner easily calculated from equation (xii.).

Thus the explanation given on the foregoing page of the mechanism of the "poisoning" action of an indifferent gas is in entire accordance with the experimental evidence.

Influence of carbon monoxide.

The carbon monoxide was prepared by the action of sulphuric acid on sodium formate and was freed from carbon dioxide by washing with caustic potash solution. The "poisoning" effect of carbon monoxide is very considerably greater than that of nitrogen. In these experiments a catalyst of higher activity was employed in order to carry out the reaction in reasonable time. The comparison between the rate of absorption of hydrogen when pure and when containing various proportions of carbon monoxide will be seen from the following figures:—

Concentration of nickel = 0.5%.

Pure hydrogen.			Hydrogen containing 0.2% of CO.		Hydrogen containing 0.5% of CO.		Hydrogen containing 1.0% of CO.		Hydrogen containing 2.0% of CO.

C. Theoretical curve for 3% diluent gas (drawn from equation xiv.).

Fig. 3.

The above results are shown graphically in fig. 4.

Fig. 4.

In the experiments of the first series, with 0.2, 0.5, and 1.0% CO, the carbon monoxide was almost completely converted into CH_4 , while with 2.0% of CO 85% of it had been so converted. Armstrong and Hilditch* obtained an almost identical result.

The products of the reaction of carbon monoxide and hydrogen, *i.e.*, methane and water, depress the

* Proc. Roy. Soc., 1919, A. 95, 144.

activity on the same grounds as nitrogen, and, in addition, the carbon monoxide, in order to undergo reaction, absorbs some of the energy emitted by the catalyst, which would have been used for the hydrogenation of the oil. Hence the very great "poisoning" effect of carbon monoxide.

Concentration of nickel = 1.0%.

Other gases investigated were found to fall naturally into one or other of the three groups mentioned, which furnish a convenient classification of gaseous catalyst poisons:—

(a) Gases of which the "poisoning" action is purely a physical one, consisting of two factors, namely, the lowering of the partial pressure of the hydrogen and the diminution of the power of the catalyst for absorbing or occluding hydrogen. Nitrogen is a typical example of this class.

(b) Gases which, in addition to having the physical action of the former class (either themselves or in the form of their transformation products) undergo a chemical change in the presence of the catalyst. The "poisoning" influence of this group is, speaking generally, much greater than that of the former group, a possible explanation of this being that not only do they diminish the "absorptive" power for hydrogen of the catalyst, but also, being occluded on the immediate surface of, or even dissolved in the catalyst, they absorb some of the "energy" emitted by the catalyst, becoming themselves reactive. Carbon monoxide is typical of this class.

(c) Gases which are able to react chemically with the catalyst itself, forming stable compounds at the temperatures employed. The mode of action of these poisons is self-explanatory. Hydrogen sulphide was found to belong to this class.

SUMMARY.

(1) Equations are derived for the rate of addition of hydrogen to mixtures of unsaturated glycerides, using nickel as a catalyst. The reaction between pure hydrogen maintained at a constant pressure and an unsaturated glyceride is of the first order. The more highly unsaturated glyceride (linolin) takes up hydrogen at a very considerably greater rate than olein.

(2) The rôle played by the catalyst is discussed from the results of experiments on the influence of the pressure of hydrogen and of temperature on the velocity of the reaction. It was found that the rate of saturation of olein (containing three double bonds) was proportional to $p^{1.5}$ where p is the pressure of hydrogen, which is in accordance with the view that the hydrogen becomes active through its absorption by the catalyst—Sieverts having shown that such absorption is proportional to \sqrt{p} —with a dissociation of the hydrogen molecules into atoms. The temperature coefficient of the velocity constant was found to be small, an increase of 10° in the temperature for the range investigated (120° – 180° C.) only increasing the velocity 1.13 times, thus suggesting a photochemical reaction, the molecules of olein being brought into an active

condition by absorption of infra-red radiation emitted by the catalyst—a conception of catalysis first put forward by Lewis and Lambie (*loc. cit.*) for the hydrolysis of methyl acetate in a homogeneous system, the catalyst being the hydrogen ion.

(3) The mode of action of "gaseous catalyst poisons" is illustrated and discussed. Such action may be a purely physical one, or it may be chemical in the sense that the "poison" is capable of reacting either with or in the presence of the catalyst.

In conclusion the author desires to express his thanks to Messrs. Lever Bros., Ltd., for permission to publish these results, and in particular to Mr. Buchanan and Mr. Tainsh for the great interest they showed in the progress of the investigation.

Communication.

THE SOFTENING OF PLASTIC MATERIALS DETERMINED BY THE WIDNEY RESILIOMETER AND EXPRESSED GRAPHICALLY.

BY ALAN SPEEDY.

It has long been customary to compare plastic materials by such tests as melting point, twisting point, penetration, etc. These tests in the author's opinion are valuable up to a certain point, but are not easily reproducible and do not give any indication of the various changes taking place under heat. It is for this reason that the following method has been adopted.

The instrument used for carrying out this test was the Widney Resiliometer† (Fig. 1), which was adapted so that with a presser foot, C, of $\frac{1}{8}$ in. diameter, the weight, I, gave a pressure of 200 lb. per sq. in. The metal base, D, was replaced by ebonite, in order that loss of heat through conduction should be as little as possible. The details of the machine can be seen from Fig. 1; the large dial, A, is graduated in 100 divisions, each 1-1000 in., so that one revolution of the large pointer or hand is equivalent to an elevation of 1-10 in. travel by the presser foot. When the material is more than 1-10 in. thick the hand will revolve more than once around the dial, the number of revolutions being indicated on the small dial B.

The operations are as follows:—The thickness is first determined by placing the sample between C and D, the normal thickness being read off on the dial. The spring-catch, E, is now released, holding the weight, I, and the quadrant, F, allowed to swing until the pressure is put on the upper end of presser foot, G, at the top of dial. This forces the foot into material until it reaches the limits of compression as the result of the weight applied; the reading on the dial at that time is taken and compared with the normal or original thickness. For example, a sample having a normal thickness of 100 mils (a mil = 1/1000 in.) gave a reading at 200 lb. per sq. in. of 25, i.e., at this

* Lewis has recently begun to consider heterogeneous reactions from the point of the radiation hypothesis (Chem. Soc., Trans. 1919, 115, 182).

Preparation of test piece.—A sample of convenient size for testing is 2.5"×0.5"×0.100" thick and is easily obtainable by aid of a small mould, the shape of the sample permitting several tests to be determined throughout its length.

"Softening."—The procedure is as follows:—

tained at the required temperature for a few minutes to ensure that the sample is uniform throughout. It is then quickly taken out, its compression taken and replaced in the bath, the temperature of which is then raised at the rate of about 4° F. a minute to the next reading, the sample being tested at every 10° F.

When dealing with complex substances which have no definite constant, the value of these curves will be at once apparent. The author has found the curves most instructive and of great assistance in

A. Siak gutta percha (low grade). B. Balata (low grade). C. Balata (low grade). D. Leaf gutta percha (high grade).

A. Mexican oil pitch. B. Tough oil pitch. C. Asphaltum. D. Medium coal tar pitch. E. M.R.X. (bitumen). F. Trinidad pitch.

A test piece, which should be moulded about twelve hours before testing, is placed in water at 60° F. or lower, depending on the sample, and main-

controlling running batches of material.

In conclusion, he desires to thank Mr. A. Manning for assistance in carrying out tests.

Softening.

MR. C. E. SHOLES IN THE CHAIR.

INDUSTRIAL FILTRATION.

BY HENRY B. FABER.

The first important step in the approach to a problem of filtration is the determination whether or not the solids may be separated from the liquid content by the agency of a filter medium, and for this purpose a preliminary settling test should be made. A graduated vessel filled with the slurry in question and maintained at a given temperature will give much useful information, which may be supplemented by a microscopical examination of the various particles. If there are particles in suspension which exhibit Brownian movement, I would be inclined to classify the problem as one not adapted to the ordinary methods of filtration, viz., the separation of the solid from the liquid by means of a porous medium.

Following this test, a very simple apparatus may be used in order to obtain data as to the character, size, and, in many cases, method of operation of the filter capable of handling the problem. It consists of a frame of brass tube $\frac{1}{2}$ in. in diameter, the lower side of which is perforated. Over this frame is sewn canvas or some other common filtering medium, forming a paddle or filter leaf. This leaf is approximately $3\frac{1}{2}$ in. square, having $\frac{1}{2}$ sq. ft. of active filtering surface. This test filter leaf, connected to a Woulff's bottle exhausted by a vacuum pump, is introduced into the slurry, which has been brought to the temperature at which it will be filtered, kept thoroughly agitated. The solids form as a cake upon the filter leaf, the liquid being drawn through and caught in the Woulff's bottle. After a cake of the desired thickness has been formed the leaf with the adhering cake may be removed and introduced into water, which is drawn through the cake, expelling the filtrate and washing the solids. After washing has been completed the leaf with the adhering cake is suspended in the air with the suction still on to remove excess of moisture. The cake may now be discharged from the leaf by disconnecting it from the Woulff's bottle and subjecting the leaf to a puff of air blown through its hollow frame. This simple test will supply data from which to calculate the area of active filtering surface required to handle a given problem under the prescribed conditions.

Filtering problems fall naturally into three distinct groups:—

The first group embraces those slurries in which the suspensions are fine, but not of a colloidal character; those slurries which contain slow-filtering suspensions in large or small bulk; and those slurries which by reason of a relatively small amount of suspended matter require merely clarification.

The second group embraces those slurries containing relatively free-filtering suspensions—slurries which permit the liquid content to be separated readily from the solids, where the solid content is of considerable bulk, crystalline, or definite in its form.

The third group embraces those slurries which are principally mother liquors, containing relatively large crystals, in which the liquid content can be drained readily and the crystals washed easily, the principal problem being the automatic and easy handling of the solids.

In the first group, in which the suspensions are fine and the slurries slow in filtering, the engineer has two problems confronting him—the problem of large area of filter surface and that of keeping the filter surface clean. The filter press is probably the best known type of filter equipment in use.

A process of filtration invented by George Moore has been extensively employed in metallurgical work. This process involves the use of filter leaves, operating in an open tank. These leaves are frames of pipe, usually rectangular in shape, over which are sewn filter cloth completely encasing the frames and forming a hollow shallow chamber with ribs spaced equidistant across the face of the leaf to prevent the two faces of the cloth from touching. The pipe constituting the lower edge of the frame is perforated. When the leaf is submerged in the slurry to be filtered and suction applied, this suction is translated throughout the entire space within the leaf, causing the liquid to pass rapidly through the cloth, leaving the solids deposited upon the outside surface in the form of an adhering cake. Many of these leaves are attached to a common header, and may be enclosed in a container for use with either suction or pressure. The simplicity of this construction permits the use of very large areas of filtering surface at a relatively low cost.

Rotary Filter—Zenith Type.
(In operation.)

In reference to the handling of problems in the second group, viz., slurries which are relatively free-filtering and build a substantial firm filter cake quickly, the rotary filter is the most desirable type to use. The rotary filter made its first appearance in Belgium about fifty years ago, and consisted of a headed barrel rotating about its long axis. The face of the drum was perforated and covered with a filtering medium held in place by winding cords. This machine was used for the filtration of salts and proved very effective. Suction was applied to the interior of the drum by means of a goose-neck passing through the head of the drum and dipping down to within a short distance from the bottom. The drum rotated in a shallow container,

dipping into the slurry through an arc of about 40°. Later this type of machine was built of substantial metal construction. The perforated surface was replaced by bars of iron, forming a grating. In all cases a goose-neck dipping within the drum downward to within a short distance from the bottom, served as an exhaust and also to carry away the liquid from the inside of the drum. When the drum was rotated the filter cake, which adhered to the surface, was removed by means of a scraper.

George Moore has also invented a multiple-compartment or rotary filter, in which the peripheral surface of the drum is composed of a number of shallow hollow compartments, over which the filtering medium is stretched. Each of these compartments has its own separate pipe line connected to a valve hub, by means of which suction or pressure may be applied at will through any desired arc. These machines have had wide usage in the mining field for the handling of concentrates, and are extensively used in industrial chemical work, where automatic and continuous filtration is rapidly replacing the older methods.

In handling slurries of the character mentioned in the third group, viz., crystals from mother liquor or coarse granular suspensions, the centrifuge or draining boards have been widely used.

The rotary filter has failed in many cases by reason of the fact that the solids will form too heavy a cake and will not adhere firmly enough to prevent the cake breaking away from the drum and thickening in the container. The "rotary hopper de-waterer" is a type of filter machine built especially for this class of work and consists of a series of elongated hoppers arranged radially about a central axis, each hopper having a filter bed, below which a pipe line connects with the central valve hub, similar in design to that used in the construction of the rotary filter. As the filter beds are set quite a distance below the rim of the hoppers, they form a series of filter trays, revolving slowly about a central axis. The slurry is fed into these trays at a point about 30° from the zenith and de-watered by means of suction as they rotate through an arc of about 40°. Suction is then automatically cut off and the product discharges either by gravity or by a puff of air, making the operation continuous and automatic.

In washing the filtered solids it is important to provide against the channelling of the filter cake. In the filter press, as well as the self-dumping type, it is difficult to provide against a classification of the solids, as the heavier particles will often settle away from the lighter, forming areas of less resistance to the passage of the filtrate. This classification is not met with to any noticeable extent in the open tank type of filter, as the slurries may be kept in constant and thorough agitation during the process of filtration, thus ensuring a homogeneous slurry. Consequently, it has been my experience that washing on the open tank leaf type of filter can be accomplished with less wash-water and a more thoroughly cleansed product obtained than by either the press or self-dumping type. It seems to be a prevailing custom among engineers to determine the degree of wash that a filter-cake has been subjected to by merely testing the wash-water coming from the filter. It is much better to sample the filter cake itself, taking a number of samples from different parts in the chamber or on the filter leaf. It is also desirable, wherever possible, when extreme degrees of washing are required with a minimum amount of wash-water, to discharge the cake after the mother liquor has been replaced to a reasonable extent by wash-water, and to churn up or cream the product, thus getting the advantages of diffusion, and then to re-filter. This method of washing is particularly advisable in the

case of the rotary filter where the period of washing is relatively short, the filtration, washing, and automatic discharge being accomplished in one revolution of the filter drum. Very satisfactory results have been obtained on difficult problems of washing where only sufficient wash-water is sprayed upon the cake to replace the mother liquor held by the cake, volume for volume, and the cake discharged into an agitating tank in which it is mixed with wash-water in sufficient amount to permit the easy handling of the slurry, and re-filtered. In dealing with free alkalis the passage of steam through the cake prior to washing with water will often show very beneficial results. Many filtration problems will be simplified if more care and attention is given to the form in which the solids appear at the time that filtration is to be attempted. In other words, the chemical reactions should have run their course and the suspensions should have been allowed to form themselves in a physical condition as far as practicable, giving the best separation possible having regard to their nature and crystalline structure.

MR. L. P. WILSON IN THE CHAIR.

ON THE INFLUENCE OF THE TEMPERATURE, CONCENTRATION, DURATION OF THE MASH, AND SLACKNESS OF MALT ON THE STARCH PRODUCTS OF THE EXTRACT OF MALT.

BY JAMES O'SULLIVAN, F.I.C.

In a communication to the Institute of Brewing "On an Improvement in the Method of Malt Analysis" (J. Inst. Brew., 1911, 17, 35; see this J., 1911, 230) I showed how by the standard method of mashing the starch of malt could be estimated and the relative quantities of its transformation products determined in the mash extract. The mashing conditions in that work were mainly in accordance with the standard method of malt analysis (J. Inst. Brew., 1906, 12, 1; see this J., 1906, 236). I now purpose showing the influence which variations in the conditions of mashing have on the composition and behaviour in a fermentation of the transformation products of the starch.

It must be clear to anyone who has followed the method of working described in the paper above mentioned that if the sucrose, always present in malt, were inverted during the time allowed in the standard method of mashing an error would be introduced to the extent of the invert sugar produced. Although I then pointed out that during the time of mashing none of the sucrose was inverted, and that slightly more sucrose was found in the mash extract than in the alkaline water extract, yet I consider it useful to give further proof of this. When malt is extracted with water at 20° C. for three hours, with or without agitation, I have invariably found that the extract is greater and has a higher cupric-reducing power than when the extraction is made with alkaline water, as in the standard method of malt analysis.

That the higher cupric-reducing power of the

water extract is not due to inversion of the sucrose of the malt during the extraction was proved by heating a volume of that extract to 100° C. and estimating its sucrose content by the method described by me (*loc. cit.*), when it was found that it contained the same amount of sucrose as the alkaline water extract. The cupric-reducing power of the water extract, or that of the alkaline water extract, is not altered by boiling either of these extracts. These facts prove that invertase is not present in malt.

By simply grinding a quantity of malt in the presence of water, in a specially-constructed apparatus, I found that it yielded to the water an amount of maltose equal to 63% of the starch it contained, allowance being made for the cupric-reducing power of the sugars present in the malt.

By grinding in a similar manner potato starch, and also malt starch, with prepared diastase, in the former case for two hours and in the latter for fourteen hours, it was found that the cupric-reducing power of the portion that went into solution—calculated as maltose—amounted respectively to 17.4 and 70.4% of the starches employed. (See also J. L. Baker and H. F. E. Hulton, *Chem. Soc. Trans.*, 1914, 105, 1529; this J., 1914, 760.)

The results of many similar experiments with starches showed that the optical activity of the starch products so obtained is much less than that calculated from their apparent maltose and dextrin content, after correcting for the quantity of diastase and its very slight levo-rotatory power.

I conclude from the foregoing that the greater extract and the higher cupric-reducing power of the water extract of malt over that obtained by the alkaline water method of extraction is due to solution of the starch granules and not to the inversion of the sucrose.

At present I am prepared to state that apparent maltose and dextrin are not the sole products of the action of diastase in the cold on either malt or potato starch "granules." However, I find no evidence of the presence of dextrose in what goes into solution, as I failed to obtain an insoluble osazone. The osazone test for small quantities of dextrose in presence of relatively large quantities of starch products, or of maltose, is, I find, a complete failure.

In order to establish the absence of invertase from ordinary malt I give in Table 1 the amount of sucrose found in 10 malts obtained by the two methods of extraction stated in that Table.

Table 1.

9	5.3	65°	5.2
10	4.9	65°	4.7
			4.6

On comparing the numbers in columns 2 and 4 above there can be no other conclusions than:— (1) That sucrose is not inverted in the process of mashing, and (2) that invertase is not present in malt. I have already proved (*Trans. Laboratory Club*, 1890, 3, 5; this J., 1890, 535) that invertase is present in germinating barley, and (*J. Chem. Soc.*, 1900, 77, 69; this J., 1900, 386) have established its presence in all parts of mature plants of the gramineae. Invertase and sucrose are present in malt culms, but invertase cannot be to any extent extracted by water from them. Malt culms contain as much sucrose as malt.

The absence of invertase from malt, and also lipase as proved by me (*loc. cit.*), makes the way clear for determining the influence of varied conditions of mashing on the starch transformation products of malt.

In Tables 2, 3, and 4 the numbers given, other than those in columns 9, 10, and 11, were obtained by the mode of procedure already described (*loc. cit.*).

Cold water extract was obtained by digesting 25 grms. of the ground malt for three hours at 20° C. in 250 c.c. of alkaline water containing 20 c.c. of N/10 potassium hydroxide. The specific gravity of the filtrate from this digestion was determined, and also its cupric-reducing power, gravimetrically, by using 10 c.c. and calculating this as maltose per 100 c.c.

Mash extract.—50 grms. of the ground malt was introduced directly into a 515 c.c. (Heron's) flask and placed in a water bath kept at a temperature 2° C. above that of the required mashing temperature. The malt in the flask was heated to 60°–61° C., and when the quantity of mashing water used was 360 c.c. this was added to the malt at 3° above the required mash temperature; when 134 c.c. of mashing water was used, this was added at 6° above the required mash temperature. The temperature in column 3 in the Tables was actually that of the mash for the time stated until it was heated to 75° C. for 10 minutes.

The mash in the flask was cooled and made up to 515 c.c. at 15.5° and filtered. The specific gravity of the filtrate and its cupric-reducing power, employing 3 c.c., were determined and the latter calculated as maltose per 100 c.c.

We have so far four factors: *a*, the specific gravity of the mash extract; *b*, that of the alkaline water extract; *c*, the cupric-reducing power, as maltose per 100 c.c. of the former; and *d*, that of the latter. From these factors we arrive at the composition of the starch transformation products at the temperature of the mash, and also at the amount of starch in the malt in the following manner.

$a-b$ =the specific gravity of the mash extract which is due to the starch products, and $c-d$ =the grms. of maltose in the starch products of the mash extract.

The specific gravity above water of $(a-b) \div 4$ equals the grms. of starch product per 100 c.c. in the mash extract. For the strength of this extract the divisor 4 is nearer the truth than any other divisor. There is, however, a slight, unimportant correction to be made here. From numerous determinations of the quantity of soluble albuminoids in the cold water extract and in the mash extracts of malts I find that the latter contains an average of 0.04 gm. of albuminoids ($N \times 6.25$) per 100 grms. of malt more than the former, and therefore the correct number for the starch products is $\frac{1}{4}(a-b) \div 4 - 0.04$ grms. of starch products per 100 c.c. (*e*).

Then $(c-d) \times 100 \div e$ = the percentage of maltose in the starch products (column 8).

The dextrin is obtained by deducting the grams of maltose from the starch products, and the maltose divided by 1.055 gives the starch equal to the maltose which, when added to the dextrin, gives the starch in 10 grms. of malt (column 6). One grm. of starch = 1.055 grms. of maltose.

The "transforming power" of the malt (column 7) is expressed by the percentage of starch which is converted into maltose.

As an example, the numbers obtained for a malt were: *a* mash extract sp. gr. 1028.70, *c* = 4.833 grms. maltose per 100 c.c.; *b* cold extract sp. gr. 1007.49, *c* = 0.734 grm. maltose per 100 c.c.; due to starch products $1021.21 = 4.099$ grms. maltose per 100 c.c. Then $(21.21 \div 4) - 0.04 = 5.26$ grms. of starch products per 100 c.c., and $(4.099 \times 100) \div 5.26 = 77.8\%$ of maltose on starch products, $5.26 - 4.099 = 1.161$ grms. of dextrin, and $4.099 \div 1.055 = 3.885$ grms. of starch; and 1.161 grms. of dextrin + 3.885 grms. of starch = 5.046 grms. of starch in 10 grms. of malt, or 50.46%. The transforming power of the malt is $(4.099 \times 100) \div 5.046 = 81$.

The extract of 10 grms. of malt in 100 c.c. was fermented with yeast at 22° C. for 5 days and shaken every day. On the sixth day—fermentation having apparently ceased on the third—the fermented extract was evaporated, cooled, and its volume (yeast in) made up to the original volume at 15.5°. In order to avoid filtering out the yeast the extract, when made up to the original volume, was transferred to a beaker and allowed to rest, covered overnight; the yeast having subsided in that time, the supernatant liquid was poured off and its specific gravity determined. The degrees of gravity before fermentation, less those of the residue, give the degrees fermented, from which the percentage of extract fermented is obtained, which is given in the tables (column 10).

In carrying out the fermentation of the extracts it was immaterial whether primary yeast (*Saccharomyces cerevisia*) or secondary (*S. pastorianus*) was employed, or whether an excess of these ferments, or a growth of either was employed, the amount fermented being the same in all cases. By a growth of yeast I mean starting the fermentations with a small quantity.

The fermentation of the alkaline water extract (cold-water malt extract) after neutralisation and boiling was carried out as in the mash extract; and although the whole of the cupric-reducing power of this extract disappears on fermentation, there was a slight phosphate precipitate obtained from the unfermented residue, which was filtered off and treated as if it were cuprous oxide. Allowance was made for this in all determinations of the cupric-reducing power of the extracts.

The degrees of gravity fermented of the cold-water malt extract, together with the degrees corresponding to the maltose found in the mash extracts, give the total, which, for my purpose, is calculated as fermentable, and from which the percentage fermentable given in column 9 is deduced.

The amount of the starch products fermented (column 11) is obtained by deducting the degrees of gravity fermented of the cold-water malt extract from the total degrees fermented of the mash extract; the difference is due to the degrees of gravity corresponding to the starch products fermented.

I have allowed—though this is unimportant—for the gravity of the albuminoids in the mash extracts over those in the cold-water malt extract by deducting 0.16 from the difference between the gravities of the two extracts.

The percentage of starch products fermented (column 11) is equal to (degrees of gravity fermented in mash extract—degrees of gravity fermented in cold-water malt extract) $\times 100 \div$ degrees of gravity due to starch products in the mash extract.

5	134	65-66	3							
6	134	69-70	3							

On examination of the average results in Table 2, where 360 c.c. of water to the 50 grms. of malt was used—thin mash—and the temperature varied, it will be seen that as the temperature diminishes the transforming power increases, and, as a matter of course, the calculated fermentable matter increases, but the amount fermented does not in-

crease in proportion. It will also be noticed that the amount of starch products which ferments is greater than the maltose they contain, and that this is not so marked in the low temperature series of experiments. The inference is, as we know of old, that apparent dextrin is fermented.

When the results in series 4 of experiments—the variation being in the volume of water (thick mash)—are compared with series 1 we find that the transforming power and the fermentable are, for all practical purposes, the same, but the fermented is 6.9, and the fermented of the starch products is 10.1% less than in series 1, and the fermented of the starch products is less than the maltose they contain.

A comparison of the results in series 5, in which the stand of mash was 3 hours, with those of series 4 of 1 hour shows that the transforming power is 8.8, the fermentable 6.7, and the fermented 12.1% higher than in series 4, and also that the starch products fermented are 17.4% higher than in series 4 and greater than the maltose they contain.

The results in series 6, in which the mashing temperature was 69°–70° C., are much lower than in series 5, and the starch products fermented is above the maltose they contain.

In all of the unfermented residues both maltose and dextrin were present, consequently it must not be inferred where the amount of starch products fermented is less than the maltose contained in them that only maltose, and not all of that, is fermented. Apparent dextrin and apparent maltose fermented in all, but I am only concerned with the amount fermented of the malt extract.

The results in Table 3 are from four malts according to the condition of series 5 of experiments, and it will be seen how greatly they differ from those of that series. It will also be noticed that in mashing at 60°–61° C. the starch is not all dissolved in malts 2 and 3. These were foreign, thin and steely, low-class malts, and were chosen to see if the starch products yielded by them, and the behaviour of these on fermentation, would show

any great variation. The results are shown to differ, and there is no analytical method yet devised, other than that here described, by which the difference, on mashing, in the starch products of these malts could be revealed. It will be observed that a fermentation of the extract is necessary in all cases in order to disclose if a malt when mashed will yield high, not easily fermented, or low, easily fermented, types of starch products.

Matthews and Auty (J. Inst. Brew., 1907, 13, 685) in a very exhaustive work on the influence of the temperature of the mash on the composition of the extract, experimented at mashing temperatures of 60°–65.6° C. with a 10% malt-to-water mash and a two hours' stand.

The results I have given are on the basis, in the thin mash, of practically 14% and in the thick mash of 37% of malt to water, and at the expiration of the time of stand the entire mash was heated to 75° C. for 10 minutes.

Matthews and Auty did not raise the temperature above that of the mash before filtering, consequently active diastase would be left. As the time taken to filter the volume of extract they dealt with would be very much longer than that of the stand of the mash, I infer that although under their conditions of working their results are in themselves practical and comparative, yet they cannot be looked upon as showing the influence of the temperature of the mash on the composition of the wort. The higher the temperature of the mash the less would be the diastatic action during its filtration when not heated to a temperature sufficiently high to stop the diastatic action.

The quantity of moisture in malt has, from time immemorial, been looked upon with suspicion by the brewer. Excessive moisture in malt indicates long and imperfect storage, and, in my opinion, it is absurd to ascribe this, under ordinary conditions of transit, to be due to moisture absorbed during transit.

The following experiments were made in order to answer the question: Has slackness of malt any influence on the composition and character of the starch transformation products of the extracts when such a malt is mashed?

A weighed quantity of malt containing 3.9% of moisture was placed in a wide-mouthed bottle and kept stoppered; another weighed quantity of the malt was placed in a similar bottle and kept unstoppered. From time to time the malt in the open bottle was well mixed and weighed. After the lapse of six months this malt was found to have absorbed only 6.8% of moisture, making a total moisture content of 10.7%. The malt kept in the closed bottle for the same time had only absorbed 0.17%. I will call the former "dry malt" (D), and the latter "slack malt" (S). To aim at the same amount of extract from the slack malt 53.4 grms. is required where 50 grms. of the dry malt is used.

Table 4 gives the results obtained in experiments S 1 and S 2 for the slack malt, and in D 1 and D 2 for the dry malt; and in D 3 the results for the dry malt 19 months after the results S 1 and 2 and D 1 and 2 were obtained.

A second malt containing 3.9% of moisture on March 20, 1911, was used, and the results, D 4 and D 5, were obtained for it at the date. Some of this malt at this date was put into a wide-mouthed bottle and a ball of moist cloth was suspended over it in the bottle.

The cloth was kept moist, and from time to time the malt was taken out of the bottle and mixed. On May 11, 1911, the moisture was found to be 8%, or an increase of only .41% in spite of ex-

posure to a moist atmosphere for nearly two months. The malt at this date was sealed up in a bottle, as was the original malt on March 20, 1914.

The results obtained for these malts on November 9, 1914, are given in Table 4, experiments S 6 and S 7 and D 8 and D 9. The results of S 1 and D 1 one hour stand show a difference in the transforming power and, consequently, a difference in the composition of the starch products, and although there is less fermentable in D 1, more of the extract ferments and of the starch products than in S 1, but in S 2 and D 2 the results are practically the same. In D 3 the results obtained for the same malt kept for 19 months show the transforming power to be practically the same as in S 2 and D 2, but the fermented of the extract and of the starch products is less. The average of the two experiments with the second malt on March 20, 1914, D 4 and D 5, and the two experiments on Nov. 11, 1914, D 8 and D 9, are practically the same, but the results on Nov 11, 1914, S 6 and S 7, show the transforming power and extract to be less, but practically the other figures do not differ from those of the dry malt.

The malts were ground in a Seck mill set at 25; it was, however, found that for the determination of the alkaline cold water extract of the slack malt this method of grinding gave low results unless the malt was passed many times through the mill. There is little doubt that the difference between the extracts of the slack and dry malts is also due to the fact that the former does not grind as fine, under like conditions, as the latter.

Table 4.
"Slack" and "dry malt" compared.

The malts—slack and dry—the results of which on Nov. 9, 1914, are given in Table 4, Expts. 4

to 9, were sealed up in bottles on that date. On June 26, 1916, they were mashed exactly as on the previous date. The results then obtained are given in Expts. D 10 and S 11. It will be seen that the transforming power in each case is less than on the previous date; the composition of the starch products is altered, less apparent maltose is present, the amount fermentable is the same, but the amount which actually fermented of the extracts is greater.

It will also be noticed that all the numbers for transforming power obtained for the second malt in the Expts. 4 to 11 are much above what is considered to be a resting stage in starch transformations; that is, 84% of maltose on the starch, and in Table 3 for the malts 1 and 4 it is less.

I observed in this work that on keeping the malts the cupric-reducing power of their alkaline water extracts diminished considerably, while the quantity of sucrose remained unaltered.

DISCUSSION.

The CHAIRMAN, alluding to the statistics, enquired whether the author had made a graph of the increase of the rate of hydrolysis with the increase of temperature or concentration. If so, what was the type of reaction indicated? Of course, there was only a small range of temperature, as there was not much activity, or fermentation, outside certain narrow limits, the reaction being quite different from the ordinary chemical hydrolysis of carbohydrates.

Mr. DUNCAN said it would appear that if the Lintner method, which had become so standardised and misinterpreted, were improved upon, a substantial advance had been made. Apparently the paper turned on the fermentation test on a miniature basis, and he imagined that subsequent to the fermentation a gravity estimation was made of the residual extract, and the result was divided by a factor. What factor was adopted? Had the author studied the question of the influence of acidity of the mash in connection with the fermentability of the products secured? There appeared possibilities of the lactic acid treatment of mashes proving effective with so-termed "stubborn malts."

Mr. J. RACE enquired if the refractometer had been used for the estimation of solid matter in mash worts instead of the specific gravity method. Did the author conclude from his experiments on slack malts that moisture had no influence on the starch transformation compounds?

Mr. F. R. O'SHAUGHNESSY said the results obtained would appear to indicate that there were considerable differences between the various portions of the dextrin. In the acid hydrolysis of starch there was invariably an appreciable discrepancy between the reducing power of the product and the rotation figures. If one fermented out the product there was always a residue which contained apparently non-fermentable matter. Did that apply in the present case?

Mr. O'SULLIVAN, in reply, said it was not possible to make the comparison as suggested by the Chairman, because instead of the action increasing with the temperature it decreased. He did not value the Lintner method except perhaps from the maltster's point of view; it merely afforded an index as to how malt was cured. It gave no information whatever as to the behaviour of the malt when mashed, and that opinion had been shared, he believed, by the late Professor Adrian Bawn. He did not think it was practicable or useful to study the question of the influence of the acidity of the mash, and he had not done any experiments in that direction. He had not used the refractometer;

he did not know that anything could be more reliable than the specific gravity for determining the amount of extract yielded by malt. There were only slight differences between slack and dry malts, but it must not be inferred that he was speaking of beer. The best quality beer, in point of flavour and character, would be made with dry malt. The acid hydrolysis of starch did not apply, as the products by acid were quite different.

THE ACTION OF WATER ON LEAD.

BY J. F. LIVERSEEGE, F.I.C., M.I.C. AND A. W. KNAPP, B.S.C., F.I.C.

It is well known that many waters act on lead. The subject was investigated by Dr. A. C. Houston, who devised the erosion test with which this paper largely deals (Moorland Waters in regard to their Action on Lead. *Vide* Supplements to Reports of Local Government Board, 1900-2).

The question is of considerable importance from the point of view of public health, and the conditions under which lead is eroded are of interest in relation to the uses of lead in the arts. The waters which Dr. Houston examined were acid in character, and notable for their power of dissolving lead. On the other hand our experiments deal with a faintly alkaline natural water which, like distilled water or pure rain-water, dissolves very little lead, but which has, in the untreated condition, the power of eroding the lead, so that scales formed on it fall away, leaving a fresh bright surface open to attack. The erosive ability was not considered by Dr. Houston to be a dangerous quality, save under special conditions and in the presence of bright lead.

The water used in the tests.

The gathering-ground of the Birmingham water supply, which provides for the needs of a million persons, is about seventy square miles of uncultivated land in Wales. Geologically it consists of Silurian conglomerate, shales, and flagstones. The water is brought by an aqueduct 73 miles long to the large storage reservoir at Frankley. The aqueduct is composed of 24 miles of "cut and cover" conduit, 13 miles of tunnels, and 36 miles of iron pipes. During the passage of the water through the tunnels a certain proportion of spring water forces its way in and is taken up, and so the water becomes less soft during its passage from Wales to Frankley. In order to avoid any risk of so soft a water acting on lead, a small proportion of chalk is added to the water at the beginning of the aqueduct; for some time about three parts of ground chalk per 100,000 was added to the water, but it was found that this was a larger quantity than the water would dissolve, and the usual addition in recent years has been about two parts per 100,000.

The following figures show the proportions of certain constituents in the waters:—

Parts per 100,000.

	Total solids.	Alkalinity as CaCO ₃ .	Chlorine in chlorides.
Water at Welsh reservoir	4	0.3	0.9
Tunnel water	21	13.0	1.2
Water at Frankley (untreated)	5	1.7	1.1
Water at Frankley (treated)	6	2.3	1.0

The following is a complete analysis of the water as supplied to the consumer (parts per 100,000):—Carbonates as CO₃, 1.44; sulphates as SO₄, 0.10;

chlorides as Cl, 0.95; silicates as SiO₃, 0.43; calcium (Ca), 1.03; magnesium (Mg), 0.18; iron (Fe), 0.08; potassium (K), 0.14; sodium (Na), 0.53; undetermined, 1.02—total solid matter, 5.90; free ammonia, 0.000; albuminoid or organic ammonia, 0.005; nitrogen in nitrates, 0.0; oxygen consumed in 4 hours at 27° C., 0.11; total alkalinity as CaCO₃, 2.1.

The alkalinity of the water was determined as follows:—To 500 c.c. of water in a porcelain basin phenolphthalein is added, and if a red colour is produced the liquid is titrated cold with N/10 hydrochloric acid. Lacmoid is then added and the titration completed whilst boiling. As calcium bicarbonate is neutral to phenolphthalein a red colour with that indicator shows that some carbonate is present, and the term "actual CaCO₃" is used to indicate this fact. The total amount of acid used is described as "total alkalinity as CaCO₃."

By the expression "the alkalinity was 2.8" we mean that the total alkalinity, expressed as parts CaCO₃ per 100,000 of water, was 2.8.

The erosion test.

This test is an estimation of the action of the water on completely immersed sheet lead. The value of the test lies in the fact that a high erosion figure is an advance warning that the water in its fluctuations may be approaching a dangerous condition. The erosion test is performed with bright lead in water with free access to air, and under these conditions a water will erode lead when it is unable to act on lead service pipes to any extent.

The kind and position of the erosion will be shown to depend on a number of conditions, the chief of which is the alkalinity of the water. Three kinds of action occur:—

1. With waters of alkalinity 0.2 to 0.6 (*i.e.*, untreated Welsh waters), and generally with treated waters the alkalinity of which does not exceed 1.5, the whole of the surface of the lead is eroded. A flocculent precipitate forms, which falls to the bottom of the tube and leaves the lead surface quite bright but mottled.
2. With treated waters of alkalinity 1.5 to 2.5, the action is usually *corrosion* rather than erosion; a loosely-held, opaque, white crust forms here and there irregularly on the lead surface. This crust appears on the upper surface of the inclined lead in the ordinary erosion test, on the under surface if the lead is placed horizontally and almost touching the glass, and on both sides if the lead stands vertically.
3. With waters of alkalinity 2.5 and over the lead almost invariably becomes covered with a dull whitish film, which appears to act as a protective coating.

Method of performing the erosion test.—The method adopted in all experiments where the details are not specified is that outlined by Dr. Houston:—

Commercial sheet lead in strips $\frac{1}{2}$ inch wide and about $\frac{1}{8}$ inch thick (one square foot weighs 13 lb.) is scraped bright with a plumber's shave hook, and cut into lengths of one inch. Each piece is rubbed with a clean duster kept for the purpose and dropped into the water without touching with the fingers. Test-tubes 6 inches by $\frac{3}{4}$ inch, reserved for this purpose only, are washed with tap water and allowed to drain.

10 c.c. of the water is poured from a cylinder into the test-tube and the strip of lead polished

with a cloth and dropped into it. The lead is now totally immersed in the water. The tube is shaken to remove air-bubbles from the surface of the lead and allowed to stand in a cupboard for 1, 3, 7, or 14 days.

(a) *If there is no evidence of erosion* the water is decanted into a 50 c.c. Nessler cylinder and the lead strip shaken with about 10 c.c. of distilled water, which is poured into the cylinder. The lead is then removed and the tube washed with 5 c.c. of dilute acetic acid (roughly decinormal) and with water until there is 50 c.c. in the cylinder.

(b) *If erosion is doubtful* the water is decanted into a 50 c.c. Nessler cylinder, the lead dropped into a funnel, and any eroded lead washed off with a jet of water into the cylinder. Dilute acetic acid is used as before.

(c) *If there is evident erosion* the turbid water is decanted into a 100 c.c. flask. The lead is shaken out into a funnel and washed with a jet of distilled water. 10 c.c. of the dilute acetic acid is put into the tube and allowed to stand a short time before it is emptied into the flask. The tube is washed with more distilled water and the flask filled up to the mark. When the solution is quite clear 50 c.c. or a smaller measured quantity is put into a Nessler cylinder and made up to 50 c.c.

Comparison is made in 50 c.c. cylinders. 5 c.c. of the dilute acetic acid (or a quantity sufficient to make the amount present up to 5 c.c.) and 3 c.c. of saturated hydrogen sulphide solution are added to every cylinder. The colour produced by the colloidal lead sulphide is matched by standards prepared at the same time. The standards are made with distilled water, except in the case of very dark waters, when it is advisable to include 10 c.c. of the original water.

The standard lead solution used is of such a strength that 1 c.c.=0.0001 gm. Pb, and is prepared from a solution a hundred times its strength, which contains 1.831 grms. of lead acetate and 10 c.c. of N/1 acetic acid per 100 c.c. Standards may be increased by 0.1 or 0.2 c.c. of the lead solution after the hydrogen sulphide has been added, but these standards are not so reliable as those to which the hydrogen sulphide is added last.

Alteration of duration of the erosion test.—At the beginning of the investigation the times of exposure of the lead to the water were 7 and 14 days, but as the figures obtained were almost identical, the 14 days' test was discarded. Thus of the 56 samples of alkalinity 2.5 to 5.1 examined during Dec., 1905, Jan., Feb., and March, 1906, 24 gave the same figure for both 7 and 14 days; the greatest difference obtained was: 7 days 0.3, 14 days 0.7 (alkalinity 3.0). The average figures for the 56 samples were alkalinity 3.1, 7 days' erosion 0.33, 14 days' erosion 0.37.

Dr. Houston suggested at least a week (Vol. 2, p. 444) as the period for this test. This is a long time to wait before determining if a water possesses high erosive ability, and experiments were performed to find if one day would not serve the same purpose. The waters used were mixtures of an untreated water (alkalinity 0.5) and a treated water (alkalinity 2.8).

The average of the results obtained from 166 samples of Frankley water in 1909 was 0.28 for

one day and 0.45 for seven days. We conclude from an examination of our figures that the one-day test gives as good an indication of erosive ability as the 7-days' test, and since the 1-day test enables us to put on repetitions whilst the water is fresh, we have adopted it for general use.

Table 1.—Comparison of 1- and 7-day erosion.

Alkalinity as parts CaCO ₃ per 100,000	Erosion (lead per 100,000)	
	1 day.	7 days.
1.4	4.4	9.0
1.7	1.7	2.0
1.9	0.3	0.3
2.1	0.3	0.4
2.3	0.2	0.3
2.6	0.2	0.3

By the expression "the erosion figure was 1.6" we mean that $\frac{1}{2}$ square inch of lead exposed to 10 c.c. of the water for one day gave dissolved and undissolved lead equal to 1.6 parts per 100,000 of water.

Irregularities in the action of water on lead.

The erosion test was always done in duplicate, and whilst as a whole the duplicates agreed well, there were occasional striking disagreements. The colorimetric comparison which is used for the estimation of the lead is liable to give some difference. The possible error on a single determination is about 10%; that is, if there is present 1.0 part per 100,000, one may find 1.1 parts or 0.9 part per 100,000, but the differences obtained were far in excess of this. Thus one water, with an alkalinity 2.0, gave 16.0, 3.2, 2.4, and 10.0. It is noteworthy that these disagreements are so rare as to be negligible with all waters except those with an alkalinity between 2.5 and 1.5. A number of experiments were performed with a view to preventing these occasional disagreements.

(1) The 10 c.c. of water was transferred to the test-tube by means of a cylinder instead of a pipette (to prevent possible contamination of the water with saliva or the breath) without advantage.

(2) As it is sometimes impossible to shake off minute air bubbles from the lead, brushing the lead free from bubbles was tried, but poor duplicates were still obtained. Also, large bubbles were allowed to remain on the lead; they did not appreciably affect the amount of erosion.

(3) In some experiments on the influence of contact with glass of test-tubes ordinary tubes were compared with those which had been coated internally with a thin layer of paraffin wax. The mean alkalinity of the water was 2.3. The results showed that the paraffin-coated tubes gave no better duplicates than ordinary tubes, and that the erosion figures in paraffin-coated tubes were higher (mean of 13 tests: paraffin-coated 4.7, ordinary 3.8).

(4) That falling dust particles or bacteria are not the cause of the disagreement of duplicates was shown by plugging the tubes with cotton-wool. It is interesting to note that, as with open tubes, if the erosion was of the crust-forming type, it still occurred with plugged tubes on the upper surface of the lead.

(5) Experiments showed that the careful selection of tubes of the same internal diameter did not prevent disagreements of duplicates if the water had an alkalinity in what may be called the critical range (1.5–2.5).

(6) The method of removing eroded lead from the lead strip by a water jet is not ideal, and an attempt was made to remove the eroded lead completely by stroking with a glass rod covered with rubber tubing. More lead was obtained, but there was no improvement in duplicates.

(7) The following points were demonstrated by the late Mr. J. A. Brown. (a) It is essential in the erosion test that the lead be dropped into the water and not put in a moist tube and the water then run in. The preliminary exposure of lead to moist air greatly increases the erosion figure. (b) Filtration of the water made no difference to the erosion figure, the presence of the ordinary organic deposit having little or no effect.

(8) *Conclusions concerning irregular action of water on lead.*—We have now shown that none of the following is the main cause of the occasional disagreement of duplicates in the erosion test: (1) air bubbles, (2) glass or diameter of test-tube, (3) dust particles or bacteria, (4) method of removing eroded lead, and (5) presence of suspended matter in the water. The subject is of interest, and might be of practical importance, because in test-tubes put on side by side under apparently identical conditions we have considerable difference in the velocity of reaction. Is it possible that these differences are due to the presence and absence of minute quantities of special electrolytes or of enzymes?—or to galvanic currents set up in the lead by metallic impurity which occurs in one inch but not in another? In this connection it will be remembered that commercial lead is a remarkably pure substance, containing on an average about 0.01% of impurity; this consists mainly of metals such as bismuth and antimony, and contains very small amounts indeed of non-metallic substances which on oxidation would produce acids. With regard to the disagreement of duplicates it should be noted that for any particular water they only occurred with those waters within a narrow range of alkalinity, and for all the waters examined within a range of alkalinity 1.5–2.5. Now it will be observed that this is the identical range which generally gives that type of action which we have called corrosion, i.e., the formation of irregular patches of a loosely-held white crust. (We find a close parallel to this in that unequal distribution of rust noticed by Heyn and Bauer (Mitt. K. Materialprüf., 1908, 26, 1–104) which occurs when iron is exposed to water containing a certain amount (0.1%) of potassium carbonate. With waters containing less than this amount there is an even rusting all over, and with waters containing more than this amount there is no rusting). Hence the simplest explanation of the disagreement of duplicates is that waters of alkalinity 1.5–2.5 are just able to coat the lead with a protective layer, and hence the smallest amount of irregular coating leaves a clean surface exposed which the water attacks vigorously. (For further support of this, see the effect of dissolved solids on erosion.)

Determining factors in erosion.

In some cases there is difficulty in drawing general conclusions, because the action appears to follow different laws according as it is erosion proper, corrosion, or formation of protective coating.

(1) *Time.*—The velocity of the reaction falls as time proceeds. Waters of low alkalinity (up to 1.5) show a greater amount, and waters of alkalinity 2.5–3.0 show slightly great amounts of total erosion, with increase of time (see Table 1). The waters of intermediate alkalinity (1.5–2.5) are irregular in action, and may reach their maximum in one day.

2. *Light.*—The action of light is to increase the amount of the action of water on lead. Ten samples of untreated water gave an average of 16.8 of lead when the tubes were exposed to daylight, and an average of 11.9 when the tubes were kept in a dark cupboard during the day of the experiment.

(3) *Water volume.*—In these experiments pieces

of lead 1 inch by $\frac{1}{2}$ inch were used in all cases. Different sized vessels were used and different amounts of water, but the height of the water-surface above the top of the lead was carefully arranged in all cases to be 1 inch.

Table 2.—Relation of erosion to water volume.

Alkalinity of water 2.0		Time of test 1 day.	
Area of water exposed to air sq. cm.	Volume of water c.c.	Lead per 100,000 of water	Total mgrms. of lead (1 sq. in. of lead exposed).
1.5	7	12.1	0.9
2.0	10	10.3	1.0
2.5	12	7.3	0.9
4.5	22	4.5	1.0
1.2	30	2.3	0.9
13.8	63	1.7	1.1
3.1	78	1.5	1.2

With waters that erode freely variation in the volume of water does not affect to any extent the total amount of lead eroded. A large increase in the amount of water appears to cause a slight increase in the total lead eroded.

(4) *Area of lead exposed.*—Dr. Houston (Vol. II., 40), performing the ordinary erosion test with distilled water and strips of lead 1 inch long and $\frac{1}{2}$ or $\frac{1}{4}$ inch wide, found that such variations did not suffice to bring out to any appreciable extent a difference in the amount of lead eroded. On repeating this experiment under similar conditions with untreated water (alkalinity 0.5) we came to a similar conclusion. However, a more carefully devised experiment gave a more decided result.

In this experiment the strips of lead were parts of a cylinder of 1 inch in diameter and rested at right angles to the bases of small glass dishes. Untreated water (alkalinity 0.4) was used, and the amount of lead eroded estimated after 4 hours.

Table 3.—Relation of erosion to area of lead.

Length of lead strips in inches.	Total area of lead strip in sq. in.	Lead per 100,000 parts of water.	Mg. of lead eroded from 1 sq. in. of lead.
With 40 c.c. of water.			
$\frac{1}{2}$	0.62	2.5	1.6
1	1.19	5.3	1.8
2	2.30	10.6	1.8
3	3.44	13.1	1.5
With 80 c.c. of water.			
1	1.19	2.4	1.6

These results show that with water of low alkalinity the amount of lead eroded varies directly with the area of lead exposed, and (as we also showed above) is independent of the amount of water used. It should be observed that in this experiment the water surface exposed to the air was large, and that the results might have been different had the supply of oxygen been less readily available (as it is in closed lead service pipes).

(5) *Area of water-surface exposed to the air.*—We found when working with small strips of lead that, within a considerable range, the area of the water-surface exposed to the air did not produce any appreciable effect on the erosion; this is shown in Table 2 on the relation of erosion to water volume. Doubtless if the water-surface was greatly reduced then the lead eroded would be smaller (see figures for erosions in closed tubes).

(6) In all our tests the lead was completely immersed, and we noted that the less the distance of the lead from the surface of the water the greater the erosion. Thus, in one experiment, the distance

was 21 mm., lead 0·8; 16 mm., lead 1·2; 14 mm., lead 5·0.

(7) *The use of sterile tubes and sterile lead.*—In this experiment untreated water (alkalinity 0·4) was used, and a number of cotton-wool plugged tubes each containing the usual 10 c.c. of water and bright lead strips were made sterile by heating for one hour in a Koch's steam steriliser. From one set the water was poured out (the amount of lead found in this water was 2·8 parts per 100,000) and 10 c.c. of fresh water put in. Another set was left untouched; both sets were examined at the end of one week.

Table 4.—Erosion with sterile materials.

Tubes and lead.	Water.	Erosion test, figure, lead per 100,000.	Mean figure, lead per 100,000.
Untreated	Fresh	53·0	
Sterile	Fresh	58·0	
Sterile	Sterile	18·0	

The above figures show (a) that the sterility of lead and tubes is not a dominant factor in determining the amount of erosion, and (b) that erosion occurs in the absence of bacteria. The probable reasons why the erosion figure with sterile water is so much less than with fresh water will be discussed later under the effect of dissolved gases.

It might be thought that with erosive waters the above test under sterile conditions was unnecessary, that the water in the erosion test must always immediately become sterile, since it is in contact with bright lead. On the contrary, we found that exposure of the water to bright lead for 6 hours did not make the water sterile, 497 micro-organisms being grown in jelly in four days from 1 c.c. of water. A similar quantity which had not been exposed to lead was liquid in that period, so lead has a considerable inhibitory power on liquefying organisms. Other experiments showed that 1 mgrm. of lead in solution present in about 12 c.c. of jelly has little effect on the number of organisms that will grow in jelly, but that 10 mgrms. of lead produces sterility.

(8) *The effect of exposure to glass.*—It was in general found that exposure to glass, whether of bottle or test-tube, lowered the erosive ability of the water. Thus a water of alkalinity 1·9 gave, after standing in the bottle 1 day, 9·5; 4 days, 0·5; 8 days, 8·3; 11 days, 0·4; 15 days, 0·6; 18 days, 0·4; 22 days, 0·3; 29 days, 0·2 (parts of lead per 100,000). It would appear from this that the passage of water through filters of broken glass would reduce its erosive ability.

Some test-tubes were found (by the late Mr. J. A. Brown) to give an alkaline reaction to phenolphthalein after standing with water for some time. These gave lower erosion results than ordinary tubes. It should always be remembered that the "erosion test" is not simply an estimation of the action of water on lead, but of water on lead in the presence of glass, although in normal tubes, as far as our results go, they indicate that for one-day experiments the order of the erosive abilities of various waters is not affected by the presence of the glass.

(9) *Gases dissolved in the water:*—

(a) *Oxygen.*—Traube-Mengarini and Scala (this J., 1910, 700) have shown that distilled water acts appreciably on lead in the absence of oxygen, the lead passing into the water in a colloidal form. With our water the presence of oxygen appears to be a necessity, at any rate if the erosion is to be considerable. We first investigated as to whether the notable difference in the erosive ability of the untreated water and the treated water was due to difference in the amount of oxygen they contained.

Table 5.—Relation of erosion to dissolved oxygen.

Water.	Alkalinity as parts CaCO ₃ per 100,000.	c.c. oxygen per litre.	7 days' erosion, Lead per 100,000.
Untreated water	0·3	7·8	58·0
Treated water (from reservoir)	2·9	7·8	0·4

Evidently the great difference in the erosions is not due to differences in the amount of oxygen present. (Oxygen is not so soluble in water containing dissolved salts as in pure water, but the quantity of dissolved salts present here would not produce any appreciable difference in its solubility.) However, the following experiment shows that the volume of oxygen dissolved in the water limits the amount of lead eroded if no more oxygen be admitted during the reaction. (This contradicts the statement of Reichardt, Arch. Pharm., 25, 858.) In this experiment glass tubes with well-fitting stoppers were used, completely filled with untreated water (alkalinity 0·3).

Table 6.—Open and closed tubes.

7 days' erosion. Lead per 100,000.			
Volume of water in tube.	c.c. oxygen per litre.	Open tube.	Closed tube, full of water.
c.c.			
13·5		16·5	12·5
14·5		17·5	12·0
13·5	7·8	24·0	15·0
14·0	7·8	24·0	12·0

These results have an important bearing on the erosion of lead service pipes, for they show that in closed tubes the amount of lead eroded only corresponds to the maximum amount of plumbous oxide or salt that could be produced by the oxygen present (thus 7·8 c.c. per litre of oxygen gives 14 parts of plumbous lead per 100,000). They also indicate that in the ordinary open tube erosion test oxygen is absorbed from the air by the water during the process. This affords an explanation of the effect of the distance of the lead from the water surface.

Influence of Carbon Dioxide on Action of Water on Lead.

(b) *Carbon dioxide.*—The carbon dioxide for these experiments was prepared by dropping pure dilute sulphuric acid into pure sodium bicarbonate. The gas was washed by bubbling through distilled water. The curve below summarises the results obtained. All the erosions were determined under the usual standard conditions of 24 hours. The waters were various samples of untreated water with an

alkalinity of 0.4 into which carbon dioxide had been passed. (It is worthy of note that on passing the carbon dioxide through the water a decrease in colour was observed. It has been suggested that the passing of air through the water decreases the colour by oxidation. The decrease in the above experiment cannot be due to oxidation, and it is possible that the colouring matter is of a colloidal nature and is precipitated by the carbon dioxide.)

The above curve shows that for waters of low alkalinity (0.4) the increase of carbon dioxide produces little effect until as much as 1% is present, so that in all probability with our ordinary treated and untreated waters carbon dioxide is not an important factor in erosion. From 1 to 2% of carbon dioxide causes a sudden change, for this quantity is sufficient to prevent "erosion" and to cause "plumbo-solvency," i.e., the lead precipitate ceases to appear, lead bicarbonate being soluble. It is noteworthy that with this change there is a sudden fall in the total amount of lead found in the water (compare Müller, J. Chem. Soc., 1888, 54, 225, who appears to have thought there was no action since there was no visible erosion.)

According to the equation—

two volumes of carbon dioxide are required to one of oxygen, and when this ratio is exceeded some bicarbonate will be formed. In the water experimented upon we have about 0.8% of oxygen present, so that we might reasonably expect the type of action to change as soon as the carbon dioxide exceeded 1.6%. As the percentage of carbon dioxide present increases above 2% the amount of lead dissolved increases, but even with 20% present does not become as great as the original figure for lead eroded.

Table 7.—Influence of carbon dioxide on erosion with water of alkalinity 1.9 to 4.0.

Alkalinity as CaCO ₃ per 100,000	Carbon dioxide % by vol.	Erosion, Lead per 100,000 in 1 day.	Description.
1.9	trace	1.1	Erosion
2.1	11.4	4.0	Plumbo-solvency
2.9	trace	0.1	Erosion
2.9	1.0	0.2	Plumbo-solvency
2.9	2.0	0.6	Plumbo-solvency
2.9	10.0	1.6	" "
2.9	20.0	3.2	" "
4.0	trace	0	" "
4.0	11.4	2.3	Plumbo-solvency

With the exception of the first the waters given above, even when they contained only a trace of carbon dioxide, were of sufficient alkalinity not to "erode" lead. As with the waters of alkalinity 0.4, the addition of carbon dioxide produced plumbo-solvency, but with these waters of higher alkalinity more free carbon dioxide was needed to dissolve the same quantity of lead. The figures are sufficiently high to show the danger of allowing soda water to remain in contact with lead pipes.

Table 8.—Influence of carbon dioxide in presence and absence of air.

	Stoppered tube.	Open to air.
	Lead in one day.	
Original water	—	11.0
Boiled one hour	0.6	0.7
Boiled water with 32 v. v. CO ₂	1.6	3.5
	Lead in two days.	
Boiled one hour	0.8	0.8
Boiled water with 32 v. v. CO ₂	4.0	10.0

The alkalinity of the water was 0.5. We see from the above:—

1. That if the water is boiled, the lead put in it gives an erosion of only 0.7 (Houston found a similar result). It is evident from this that it is not a fixed non-volatile acid which causes erosion. It was found that if water were boiled for 1½ hours and then allowed to cool for ½ hour it contained 0.6—0.7 c.c. of oxygen per litre, which is quite sufficient to account for the 0.8 of lead obtained with the closed tube. That boiled water of alkalinity 0.5 should give so low an erosion as 0.7, although freely exposed to the air, is a little remarkable. The boiled water appears to have rendered the lead "passive." The appearance of the lead was quite peculiar; it was still bright, but had a slight bronze tarnish. This may have been a thin film of red lead, and would seem to support the conclusions of Dunstan and Hill concerning passivity (Chem. Soc. Trans., 1911, 99, 1853—1866).
2. The figures above also show that water containing carbon dioxide does not dissolve lead so rapidly if a supply of oxygen is not available. This is to be expected, since the hydroxide of lead is more readily soluble than the metal in carbonic acid.

The question may be asked if the presence of carbon dioxide is necessary for erosion to occur. All the evidence we have goes to show that it is not necessary. It will be shown later that erosion takes place readily in the absence of free carbon dioxide; for example, when 1 to 200 parts of calcium hydroxide per 100,000 are present (see curve below). And further, erosion takes place less readily in the presence of bicarbonate and carbon dioxide than with carbonate and hydroxide alone. Under normal conditions for ordinary waters carbon dioxide is an unimportant factor. We have seen that variations in the amount of carbon dioxide from 0.02 to 0.20% do not affect the erosion figure to any extent.

(10) *Liquids dissolved in the water.*—In a number of erosive waters that Allen examined he found free sulphuric acid. This could not be present in our water, for when our water showed acidity to phenolphthalein this acidity was always lost on boiling. This acidity is due to carbon dioxide, and was generally equivalent to about 0.02% of gas. Although the general principles underlying erosion were stated by Müller as early as 1888, in recent years it appears to have become a commonly accepted idea that natural waters erode lead by means of the peat acids which they contain. Our water was always alkaline to lacmoid; that is, it always contained free alkali at least as strong as bicarbonate. Further, a large number of samples were alkaline to phenolphthalein, and many of these eroded lead, so that in these cases at any rate the erosion was not due to free organic acids. The assumption of organic acids as the cause of erosion is quite unnecessary, since water, oxygen, and carbon dioxide will readily account for the observed phenomena.

(11) *Solids dissolved in the water.*—We were principally interested in these with a view to the most effective treatment of the water to prevent erosion. For example, nitrates are said to accelerate erosion. As our water never contained more than a minute trace we neglected them.

A number of experiments were performed with calcium hydroxide and carbonate and bicarbonate. Pure lime was dissolved in the untreated water, and this was mixed in various proportions with untreated water through which carbon dioxide had been passed. With these mixtures the standard erosion test for one day was made with the following results:—

Influence of Lime and Calcium Carbonate and Bicarbonate on Erosion.

The results given above show that:—

1. As the amount of *calcium hydroxide* present in the water increases, the amount of lead eroded falls to a minimum when there is present about 7 to 10 parts of calcium hydroxide per 100,000. After this point increase in the calcium hydroxide causes increase in the erosion, which gradually attains about its original amount.
2. As the amount of *calcium carbonate* and *bicarbonate* present in the water increases, the amount of lead eroded continually falls.
3. *Calcium bicarbonate* is by far the most effective preventer of erosion. Only about half the quantity of bicarbonate is required to form a protective coating as compared with carbonate. This would receive a theoretical explanation if, as seems probable, the coating is a carbonate of lead. As little as two parts per 100,000 of calcium bicarbonate is generally sufficient to form a plumbo-protective coating on the lead. Assuming that the actual coating is lead carbonate, it would form a layer only 0.000016 cm. thick. As suggested above, the irregularities that are observed in the erosion with water about this alkalinity may be due to the fact that the deposit does not quite cover the lead surface and leaves a little bright lead open to the ordinary erosive action.

All these results refer to calcium compounds; but, considering that the solutions are dilute, it is probably safe to infer that the results would be similar with all metals of the alkalis and alkaline-earths, and for similar concentrations of CO₂ and OH ions.

The untreated water taken from the Caban reservoir in Wales has an alkalinity of about 0.2, the erosion for one day is about 14. From December 6, 1905, to January 31, 1906, the alkalinity of the treated water at the Birmingham reservoir at Frankley was never below 2.7, while the erosion in seven days only exceeded 0.5 on three occasions, and that slightly. On the other hand, from May 12 to June 17, 1906, the alkalinity of the water at Frankley was uniformly low, never rising above 1.8. During that period the erosion of the water was high, being only as low as 0.5 on four occasions, while it frequently reached 2.0, and rose as high as 18.0. These results show that as a rule water of high alkalinity has a low erosion and *vice-versa*.

As potassium permanganate is sometimes put into water we investigated its effect on the erosion of

lead. We found that as little as 5 parts per 100,000 of water were sufficient to form a protective coating and prevent erosion.

Conclusions concerning erosion.

1. The waters collected in the Caban reservoir, Elan Valley, Wales, have a slight alkalinity due to bicarbonates etc. equal to about 0.3 part CaCO₃ per 100,000. Their action on lead is mainly "erosive."
2. "Erosion" is due to the action of oxygen in the presence of water.
3. Such variations as occurred naturally in the percentage of oxygen present in the water produced no appreciable effect on the erosion.
4. One day is the most suitable period for the erosion test.
5. Exposure to glass lowers the erosive ability of the water.
6. The greater the depth at which the lead is immersed in the water, the slower the erosive action.
7. The velocity of erosion falls as time proceeds.
8. Variation in the volume of water does not appreciably affect erosion.
9. For the untreated water the amount of lead eroded varies directly with the area of lead exposed.
10. Small changes in the area of the water surface produce no appreciable effect on the erosion.
11. Erosion readily occurs in waters which contain no carbon dioxide.
12. Such variations as occurred naturally in the percentage of carbon dioxide present in the water produced no appreciable effect on the erosion.
13. The presence of from 1 to 2% of carbon dioxide causes a sudden change from "erosion" to "plumbo-solvency."
14. Carbon dioxide dissolves lead more rapidly in the presence of oxygen.
15. Given oxygen the alkalinity of the water is the principal factor determining the amount of "erosion."
16. Not only the amount but the kind of erosion depends chiefly on the alkalinity of the water.
17. The addition of small quantities of calcium hydroxide, carbonate and bicarbonate, or of potassium permanganate, decreases erosion.
18. Calcium bicarbonate is the most effective preventive of "erosion," as little as two parts per 100,000 being generally sufficient to prevent erosion.
19. Erosion occurs in the absence of bacteria.
20. The bacteria in the water are not all destroyed by exposure to lead for 6 hours.

Discussion.

The CHAIRMAN asked if the authors had used chemically pure lead in their experiments as well as the ordinary commercial lead. There might be considerable difference found in the amount dissolved by comparing the effects on two leads. Chemically-pure lead almost entirely resisted both dilute and strong sulphuric acid. Commercial lead gave way much more readily. He also enquired what the effect of varying temperatures was on the erosion. The variations of effect of water of different alkalinity reminded one also of the irregular behaviour of acids of varying strengths in the dissolution of metals; with iron there was a much greater effect with dilute than strong acid. In the case of aluminium small amounts of impurity caused a much greater dissolution of the metal to take place; for instance, a small amount of nitrogen getting in through faulty treatment during casting greatly increased the amount of solvent action.

Mr. H. SILVESTER said that having frequently to test the action of water on lead he had found it satisfactory to adopt the Birmingham water as a standard for comparison. His experience showed that after 24 hours of exposure of new bright lead only one part per million, or less, of lead was taken up by the Birmingham supply, which he considered satisfactory, as with such a result under practical conditions none was found in the water as distributed. This was in agreement with the results given in the paper. As to the use of various chemicals to prevent lead attack, he found that where a quick result apart from cost was required, small quantities of sodium carbonate were effective, an alkalinity of 2 or 3 grains per gallon destroying the lead-solvency powers of the water.

Mr. J. RACE said that our knowledge of corrosion and erosion of lead had been more or less chaotic, and several conflicting hypotheses had been suggested. Heap (this J., 1913, 771, 811, 847), after a large number of experiments, concluded that oxygen was the predominating factor; while at a meeting of the American Water Works Association, which he had attended some years ago, the general opinion was that carbonic acid was the causative agent. The practical importance of the subject could not be over-stated. Whether iron pipes or lead pipes were used, there was the ever-increasing danger of corrosion due to electrolysis, consequent upon the larger use of electricity. He asked what was the effect of the seasonal flora in the reservoir. During certain seasons there should be a definite turnover of the water which caused variations in the oxygen and carbonic acid content and might produce a variable effect on lead. He suggested that the effect of water on lead should be studied in conjunction with hydrogen-ion concentration, as it was possible that this method would give better correlation with the amount of lead eroded and dissolved. It had often been assumed that, because a water was alkaline to the usual indicators, it contained no free carbonic acid, but recent work on dissociation has shown that this view is incorrect. If carbonic acid was a contributory factor to plumbo-solvency, a definite hydroxyl-ion concentration might be found that would arrest the action. Another point of importance was the nature of the pipe used for carrying the water. Waters that attacked lead pipes also attacked iron ones, producing what was known as "red water" trouble; they also dissolved the zinc coating of galvanised pipes, and so produced zinc poisoning. The Local Government Board had some years ago refused to sanction the use of galvanised pipes for drinking services in a large town on this account. In America these difficulties had led to the use of copper and brass pipe. It was found that the cost of installation was not prohibitive, because the absence of incrustation led to smaller friction losses and enabled pipes of smaller dimensions to be used. In the industrial area in North-East Lancashire he had found that the acid in the atmosphere gave a marked acid character to the rain water and was sufficient to produce plumbo-solvency.

Dr. E. B. MAXTED enquired as to the influence of agitation on the rate of solution of lead; agitation might loosen any protective deposit that might be formed and accelerate solution.

Mr. F. R. O'SHAUGHNESSY said that although the authors had shown that lead was acted upon by sterile water, it seemed possible that biological action might exert some influence. Had the authors investigated the question in relation to chlorinated waters? There was no object in preventing entirely lead from going into the water if the expense was so great and if small traces did not in any way prejudice public health.

Mr. J. O'SULLIVAN asked if the water was alkaline or acid at its source. In the North of England waters from a peaty source were treated with calcium carbonate to prevent the solution of lead.

Mr. ASHMORE suggested that if copper and zinc were kept entirely immersed they became passive; in other circumstances that was not so.

Mr. F. H. ALCOCK remarked that in one of the results it was shown that about one-fifth of the solid components of the water was not determinable. What was the amount of sulphate present?

Mr. KNAPP, in reply to the discussion, said that the tests were made with ordinary commercial lead, which was extremely pure—the amount of impurity probably did not exceed 0.01%. He had not made tests as to the effect of varying temperature or of agitation. As to why they did not regard erosion so serious as plumbo-solvency, he pointed out that in the severe tests which were made the water which would erode lead would not act upon lead pipes. They had not used sodium carbonate on account of cost. He agreed as to the effect of electricity in causing erosion in lead pipes. In one case a service pipe gave high figures which were entirely due to close proximity to electric wire. So far no seasonal variation in erosive ability had been found. No doubt the erosion would be much greater if the lead was only partly immersed, particularly along the line at which air, water, and lead came together. The matter which in the water analysis was classed as "undetermined" was organic.

Mr. LIVERSEEGE also replied, pointing out that they did not now rub the lead with a duster to polish it; experiments of the late Mr. J. A. Brown showed that such rubbing could not be standardised. There would be differences in the erosive action. They preferred, therefore, to scrape the lead and lightly to dust off any lead particles. Another improvement was the use of methyl red in place of lacmoid as indicator. The addition of chalk to Welsh water was useful as, in addition to preventing any risk of lead poisoning, it also reduced the corrosive action of the water on iron. There was a difference as to the importance to health, of erosion and plumbo-solvency, and he thought this was shown by the fact that in some Yorkshire towns there had been a number of lead-poisoning cases which, as far as he knew, had been due to plumbo-solvency, and not to erosion. In some cases untreated water was used which was decidedly erosive, and the medical officer stated that he had had no trouble from lead poisoning. He thought there was considerable difference in the importance of the two actions of lead, and that the Birmingham water was free from any risk of plumbo-solvent action. The Walker-Kay test was not useful in relation to the Birmingham water. There was very little peat in the Elan Valley, and the result was a water that was neutral or slightly alkaline.

Communications.

VAPOUR PRESSURE OF ARSENIOS OXIDE IN SULPHURIC ACID SOLUTIONS.

BY F. SCHWERS.

An important item in the manufacture of sulphuric acid by the contact process is the purification and drying of sulphur dioxide, which includes bubbling through sulphuric acid. In the factories erected by the Ministry of Munitions an acid containing 0.001% As_2O_3 was at first deemed sufficient

for this purpose. But it was soon found (1916) that the activity of the catalyst decreased rapidly, and suspicion arose as to whether part of these minute traces of white arsenic had not found their way to the catalyst. Mr. K. B. Quinan, who had charge of these plants, asked Professor F. G. Donnan to investigate the matter. I undertook the work at the latter's suggestion, and wish to thank him for his advice.

At first sight it appeared rather unlikely that under the working conditions any measurable quantity of arsenious oxide could ever be volatilised during the passage of the gas, all the more as Adie states that arsenious oxide forms a compound $\text{As}_2\text{O}_3 \cdot \text{SO}_3$ in presence of sulphuric acid. Since we have no figures for the tension of As_2O_3 below 150°C . and none in sulphuric acid solution, this point could only be decided by experiment. From existing vapour pressure data for As_2O_3 from 150°C . upwards no extrapolation could be made down to 60°C . with any chance of accuracy.

A dynamical method was resorted to as the only one appropriate to the estimation of such low vapour pressures as were expected. A glass apparatus was fitted up through which air was slowly aspirated by a water suction pump, C, carefully regulated by a pinchcock, B. The volume of air was measured by a gas-meter, D, it was then dried over calcium chloride, E, freed from carbon dioxide by caustic soda, F, after which it passed through six bubblers, G, partly filled with sulphuric acid containing minute quantities of arsenious oxide. These bubblers were immersed in a water-thermostat, H, kept at about 60°C ., which is the temperature to which the washing acid rises in a large-scale plant when the hot gases are bubbling through. Then came another set of absorption tubes, I, half filled with a 10% caustic soda solution, to retain any arsenious oxide volatilised. The shape of the apparatus was

16.7°C .) The average temperature of the thermostat was 59.4°C .; since the passage was very slow, we may admit that the air was soon in temperature equilibrium with the acid, and that 2.08 cubic metres of air at 59.4°C . actually bubbled through the acid. No record of the barometric pressure was taken, but one may take it that the average was close to 760 mm.

The estimation of arsenic was made by Thorpe's electrolytic method.* It was first ascertained in this way that the caustic soda used was absolutely free from arsenic; in fact, no trace of it could be detected. But at the end of the experiment the alkali was found to contain 0.00040 gm. As_2O_3 , which had been carried over by the air. From this it is calculated that the partial pressure of arsenious oxide over a 0.015% solution in sulphuric acid is slightly above 0.00001 mm. of mercury at the temperature of 60°C .

Though very small in the absolute sense, the quantity of As_2O_3 carried away seems large under the circumstances. In order to check this first result a second experiment was started by filling the bubblers with a sample of the very acid used in the factory, without any further addition of arsenic beyond the 0.001% it already contained. In the course of 1390 hours there passed 3.36 cubic metres measured at 15.0°C . (=3.93 cubic metres at 61.0° , average temperature of the thermostat). This time 0.000050 gm. As_2O_3 was found in the caustic soda solution, i.e., 0.000013 gm. per cubic metre at 61°C .

By comparing with the first experiment, where the arsenic concentration was 15 times greater, it is seen that the amount of arsenic carried away as vapour is almost exactly 15 times larger. Such remarkable agreement was hardly to be expected, and is partly due to chance; in fact, the probable

so devised as to prevent any actual spraying of acid into the absorbing part (see fig.). Moreover, a vertical column of glass-wool, K, was interposed between the acid and the alkali bubblers. The first absorption tube of each set was put the other way round, so as to act as a safety valve in case of back pressure. The whole glass apparatus between A and B was sealed together; there were only two unavoidable rubber connections, one to the gas-meter, the other to the water-pump.

Two experiments were carried out.

In the first experiment a little white arsenic was added to sulphuric acid (sp. gr. 1.84), and the solution containing 0.015% As_2O_3 (as found by analysis) was put into the bubblers. Air was passed during 660 hours at the rate of 1 to $1\frac{1}{2}$ bubble per second. The volume of air recorded by the gas-meter was 1.80 cubic metres (average temperature

error in the analysis of such minute quantities of arsenic may be put at about 10%).

It is now interesting to form an idea of what this means in actual practice. Let us assume, for sake of argument, that the gas to be washed through sulphuric acid is the exact mixture ($2\text{SO}_2 + \text{O}_2$) necessary to make SO_3 . If we disregard water vapour and other impurities and assume the law for perfect gases, it is calculated that 8000 cubic metres of the gaseous mixture† passing through the drying acid with its 0.001% As_2O_3 will carry away as much as 0.1 gm. of arsenious oxide. Only a small part of this is necessary to "poison" the catalyst.

THE DETONATION OF HOLLOW CHARGES.

BY A. MARSHALL.

In my book on Explosives (1st Ed., 1915, p. 321; 2nd Ed., p. 554) I have mentioned the increased effect that is produced when an unconfined cylinder of a high explosive is hollowed out. This discovery I ascribed to Egon Neumann, as he definitely claims it in the *Zeitschrift für angewandte Chemie* of November 24, 1911, for himself and his co-workers. He says: "We have found in the last few months that if a hollow be made in an explosive cartridge on the side towards the object to be blasted the effect is increased four- or five-fold." The *Westfälisch-Anhaltische Sprengstoff-A.-G.* took out patents for the discovery (Ger. Pat. Anm. W. 36,269 of 14.12.1910; Eng. Pat. 28,030 of 13.12.1911), and in the *Zeitschrift für das gesamte Schiess- und Sprengstoffwesen* of May 15, 1914, Neumann describes it as "einen ganz neuen Weg." I have, however, learned from Professor Charles E. Munroe, of Washington, that he made this discovery many years ago and gave it a wide publicity in America (Scribner's Magazine, 1888, 3, 563-576; Amer. J. Sci., 1888, 36; Popular Science Monthly, 1900, 56, 300, 441). I therefore now wish to give the credit where it is due. Professor Munroe carried out a number of interesting experiments with these charges and found that the more he hollowed out the face resting on the iron plate the greater was the depth of the depression formed, until, when the charge was completely perforated, it perforated completely the iron plate. When he interposed such articles as a piece of lace or the leaf of a tree or a coin between the hollow charge and the plate he obtained a detailed impression of the article on the iron, the raised portions of the objects forming raised impressions. The effect is much the same when the cartridge is removed some distance from the surface of the iron or steel plate, and under water the results are similar to those in air. By tying a number of dynamite cartridges round an empty tin and firing them with a priming charge, also of dynamite, Professor Munroe was able to make a considerable hole in a stout safe, whereas a similar charge made up in the ordinary way merely produced a concavity, but no perforation (Executive Document No. 20, 53rd Congress, 1st Session, Washington, D.C., 1894).

No practical use has apparently been made of this discovery, but it is of interest as throwing a light on the nature of the detonation wave. It is evident that, although the products of detonation are gases and have a very high temperature, they must possess in the wave-front a density even greater than that of the solid explosive. The wave, consisting of such gas constantly renewed, advances through the explosive with a velocity of several thousand metres a second. Where the wave is in contact with the boundary of the explosive the gas flies off at right angles to the boundary and a fresh wave is formed of compressed air, or whatever other material the surrounding medium consists. This secondary wave is inclined to the original one, but advances much in the same way as the bow-wave of a ship. In the axis of the hollow of one of these bored-out charges the waves of highly compressed air come together with enormous violence, and necessarily produce a blast in the same direction as the original wave of detonation. This is not only much more intense than the original wave, because it is more concentrated, but it also lasts longer, with the result that the metal plate is carried right away. As one would expect, a charge with a cylindrical hollow bored in it produces quite as deep a hole, if not deeper, than one with a conical hollow. Although a

hollow charge produces a much greater local effect, it does not exert nearly so great a total shock as a whole charge, as is shown by the fact that when detonated on a lead cylinder it does not compress it to the same extent.

Section of complete cylinder 310 g. TNT. Section of hollow cylinder 247 g. TNT.

Wrought iron plate 25 mm. thick on which both charges were detonated in upright position.

Effect of hollowing-out a charge.

Although a detonation wave resembles a sound wave in some respects, it also differs in important properties. One of these is that the gases permanently change their position and do not simply swing forwards and backwards as in a sound wave. It constitutes in fact what French investigators have called a "discontinuity," because the rise in pressure is quite sudden, but of course it is more intense than a discontinuity produced by other means. When two waves of detonation meet the two opposing layers of compressed gases are obliged to spread out sideways, making a distinct line on the supporting plate. This forms the basis of Dautriche's ingenious method of measuring the velocity of detonation by means of a piece of detonating fuse.

RAPID METHOD OF ESTIMATING LEAD IN CASSIA OIL.

BY O. F. LUBATTI.

It is a well-known fact that cassia oil exported from China is contaminated with lead because the oil is sold on this market enclosed in leaden cans. It is usual to report the lead contained in such oils as "traces," the test employed being the addition of a few drops of ammonium sulphide to a solution of cassia oil in 70% alcohol. The reagent gives under these conditions a decided coloration, showing that the oil contains more than mere traces of the metal. The author, therefore, has tried to improve upon this qualitative test so as to render it of a more informative nature.

The principle is very simple and consists in the usual method of estimating lead colorimetrically by means of a solution of ammonium sulphide, which is usually attributed to Pelouze.* The fact that the reaction occurs in an organic liquid and that no other metallic impurities are present is instrumental in giving an extremely subdivided precipitate which seems to be very adapted for this kind of determination.

Procedure.—5 c.c. of the cassia oil to be tested is diluted to 20 c.c. with 90% alcohol; 5 or 2.5 c.c. of this solution is taken for the estimation according as the lead content is more or less than 0.025%, which will be determined by a preliminary test. This amount is pipetted into a 50 c.c. Nessler glass of small bore (2.5 cm.) and diluted to about 20 c.c.

* I. J. Pelouze, Ann. Chim. Phys., 1841, (3) 79, 103.

with 90% alcohol. A blank from lead-free cassia oil, obtained by distilling the commercial oil, is prepared in similar way. 1 c.c. of ammonium sulphide solution is added to both glasses, and standard lead solution (in 90% alcohol; 1 c.c. = 0.0001 grm. Pb.) added to the blank until the brown coloration produced matches the sample under examination, the liquid being stirred three times after each addition of standard lead solution by means of a piston-shaped glass rod.

The results are calculated by means of the formula $x = n \times 0.04 \div m$, where x is the percentage of lead sought, n the number of c.c. of standard lead solution required, and m the amount of original solution taken.

The tint of the solutions can be compared by looking through the Nessler glasses resting on a white tile. But better results are obtained by using a Dubosq colorimeter or the apparatus described below.

The colorimeter (see fig.) consists of a wooden foot, F, in which a white tile reflector, R, turning on a pivot is situated, above this is the body, B, of the instrument, which consists of a tube of CD section in which are introduced the Nessler glasses containing the liquid under observation. On top of the glasses is a device, D, to fit the face of the observer, similar to a stereoscope without lenses. When the face of the observer is applied to D the light can pass only through the bottom of the glasses, which are supported by a glass base; all the joints are made light-tight by means of felt washers. The upper part fits loosely on the body, and can be easily and quickly removed to permit the addition of the standard solution. As sometimes the standard and the liquid under observation show before the test slight difference in tinge, a slot, S, is situated under the glass which supports the tubes, in which glasses of suitably pale amber tinge can be introduced to match the colour of the liquids.

The accuracy of the method was tested on samples of cassia oil containing known amounts of lead. The results are tabulated below.

The values for lead found by this method are thus slightly high, the average excess found being 0.00018 grm. Therefore more accurate results would have been obtained by subtracting 0.00018 grm. of lead from the amount found by experi-

ment. As the test is only approximate the errors may be said to be well within the allowed limit and the method accurate enough for technical purposes.

A comparison of the results on five commercial oils of cassia by the method described in this

Grade of cassia oil.	Amount of lead added to 10 c.c. of oil.	Amount of lead found
0%	grms.	grms.
0.005	0.0005	0.00064
0.010	0.0010	0.00128
0.015	0.0015	0.00157
0.020	0.0020	0.00216
0.025	0.0025	0.00272
0.030	0.0030	0.00328
0.035	0.0035	0.00360
0.040	0.0040	0.00416
0.045	0.0045	0.00468
0.050	0.0050	0.00520

paper and those obtained by a method suggested by Fryer and Weston,† in which the lead is extracted by warm dilute nitric acid and estimated by precipitation as lead sulphate, gives the following results:—

Oil.	% found by gravimetric method.	% found by colorimetric method.	Difference
1	0.0566	0.0536	+ 0.0030
2	0.0524	0.0520	+ 0.0004
3	0.0494	0.0512	— 0.0018
4	0.0546	0.0520	+ 0.0026
5	0.0611	0.0592	+ 0.0019

The results agree fairly well, but the gravimetric method shows, on the average, results higher than the colorimetric method, and perhaps no nearer to the actual amount present. The cassia oil after the nitric acid extraction was tested for lead according to the method described in this paper, and found to give but a very faint discoloration, showing that the extraction had been carried out satisfactorily.

It seems evident that as very similar results are obtained both by the use of the lengthy gravimetric method and the colorimetric method, the latter, which can be performed in a very short time, is to be preferred when results are needed urgently.

Using the method described above, experiments were made on the lead-dissolving power of cassia oil. 10 c.c. of the lead-free cassia oil was introduced into each of twenty-two test-tubes together with a strip of bright lead about 1 cm. broad and 6 cm. long. The tubes were then closed with clean corks, shaken at intervals, and tested at intervals.

The amount of lead absorbed increased with the time and reached a maximum of 0.074% after one month, and then seemed to remain constant. It is noteworthy that after that period the lead content exceeds the percentage found in commercial samples, which is, as a rule, from 0.04 to 0.06%.

SOLIDIFICATION POINTS OF MIXTURES OF METALLIC CHLORIDES.

PART I.—MIXTURES OF SODIUM, POTASSIUM, AND CALCIUM CHLORIDES.

BY FRED. C. A. H. LANTSBERRY, M.Sc., F.I.C., AND R. A. PAGE.

MODERN methods of heating steel in the various operations of hardening and tempering frequently demand the use of molten baths. For the high temperatures used in hardening high-speed steel, barium chloride with or without the addition of potassium chloride is used, while at lower temperatures sodium and potassium nitrates and molten lead find frequent application. These latter materials possess fairly obvious disadvantages; hence some years ago the author endeavoured to find a mixture of chlorides which could be used for tempering operations at temperatures in the region of 600° C., which entails the use of a mixture which melts somewhere about 500° C. Reference to literature brought to light some very complicated formulæ for low-melting salt mixtures, a typical recipe being NaCl 1, KCl 1, CaCl₂ 2, BaCl₂ 1, and SrCl₂ 3 parts. This mixture was supposed to have a melting point of 500° F. (260° C.), a value which could only have been realised by leaving a considerable proportion of the water of crystallisation in the mixture. It seemed possible therefore that research would reveal much simpler mixtures, and an investigation was commenced which attained the desired object and led to results of sufficient theoretical interest to be placed on record. Samples of potassium, sodium, and calcium chlorides were obtained and their solidification points determined by the cooling curve method, using a platinum, 10% rhodio-platinum thermo-couple, which was frequently calibrated during the research at the temperatures of boiling water and of freezing tin (232° C.), lead (328°), zinc (419°), aluminium (657°), and silver (961°). The values obtained were: Sodium chloride, 785° C.; potassium chloride, 760° C.; calcium chloride, 745° C.

Fig. 1.

The solidification points of the binary systems were next investigated by the methods of thermal analysis well known to metallographists. Weights of salt corresponding to the desired composition were introduced into a salamander crucible and fused. After thorough admixture a thermo-couple was introduced into the melt and observations taken of the times required for the temperature to fall through successive equal intervals—in this case about 8° C. By plotting these time intervals as functions of the temperature, the so-called inverse rate curves in which arrest points are clearly marked, are obtained, typical examples being shown in Fig. 4.

NaCl—KCl series.

The results of the thermal analysis of this series are summarised in Table I.

TABLE I.

Test.	% components.		Freezing point, °C.
	NaCl.	KCl.	
1	100	0	785
2	90	10	760
3	80	20	735
4	70	30	709
5	60	40	697
6	50	50	652
7	40	60	652
8	30	70	662
9	20	80	690
10	10	90	715
11	0	100	760

By plotting the freezing points as functions of composition the so-called liquidus curve is obtained, and this is shown in Fig. 1.

Fig. 2.

It would appear that these two components form a continuous series of solid solutions, since none of the cooling curves showed any arrest point after solidification was complete, indicating the absence of a eutectic. The lowest melting mixture contains 55% KCl and 45% NaCl, and solidifies at 650° C.

These results confirm those obtained by Smits and de Bruyn (Proc. K. Akad. Wetensch., 1913, 557—561) and Brand (Jahrb. Min. Beih., 1911, 627—700).

CaCl₂—NaCl series.

This system was next examined and gave the results collected in Table II.

TABLE II.

Test.	% components.		Freezing point. ° C.
	NaCl.	CaCl ₂ .	
1	0	100	745
2	10	90	657
3	20	80	540
3a	25	75	508
3b	27.5	72.5	505
4	30	70	508
5	40	60	570
6	50	50	620
7	75	25	740
8	100	0	785

Fig. 3

Fig. 4.

Check analyses were made on melts and gave the figure 72.3% CaCl₂ in test 3b. This proves that with proper care the ultimate compositions can be

made to agree closely with the quantities of material weighed out. The liquidus curve plotted from these figures is reproduced in Fig. 2.

Here, again, the two components apparently form a continuous series of solid solutions, for no eutectic point was observed in any melt.

The addition of sodium chloride to calcium chloride caused a considerable lowering of the freezing point; the lowest melting mixture contains 72.5% CaCl₂ and 27.5% NaCl, and freezes at 505° C.

CaCl₂-KCl series.

The third binary series was finally examined, and the results obtained are shown in Table III.

TABLE III.

Test.	% components.		Freezing point. ° C.	Eutectic point. ° C.
	CaCl ₂ .	KCl.		
1	100	0	745	—
2	90	10	670	608
2a	82.5	17.5	615	—
3	80	20	655	615
4	77.5	22.5	695	615
5	75	25	715	600
6	72.5	27.5	720	600
7	70	30	725	—
8	67.5	32.5	725	575
9	65	35	723	580
10	60	40	713	580
11	50	50	670	583
12	40	60	590	—
13	30	70	640	590
14	15	85	710	590
15	0	100	760	—

This series presented some rather unexpected and interesting results, in so far as it is quite different from the two previous systems. The new features are that the eutectic points (of which there are two) are most marked, while the liquidus reaches a

maximum at 725° C. when the mixture contains about 70% CaCl₂. This maximum corresponds to the formation of a double compound of formula

Fig. 6.

able amount of light on this point, which will be dealt with in its proper place.

Ternary series KCl—NaCl—CaCl₂.

The usual method of graphic representation of the results obtained during the investigation of a ternary series is to plot compositions in the plane of an equilateral triangle and to plot the property (in this case temperatures of thermal disturbances) at right angles to this plane, according to the method described in detail in text-books of metallography.

Mixtures of the three salts were made up according to the compositions indicated by the small crosses in Fig. 5, in which the numerals represent the temperatures at which freezing commenced. Cooling curves were taken, the results of which are summarised in Table 4.

The graphical representation of the results takes the form of a solid model, a perspective view of which is shown in Fig. 6. But the more general method of representation of the results of the investigation of a ternary series is to draw the isothermals on the liquidus surface and project them on to the base of the model. This is shown in Fig. 7.

In this system two ternary eutectics are formed, one situated at (a) in Fig. 7, containing 70% CaCl₂, 25% NaCl, and 5% KCl, and the other consisting of

Fig. 7.

28.8% NaCl and solidified at 495° C., and this corresponds very closely with the minimum in the liquidus described in the present paper. Further, the work on the ternary series throws a consider-

30% CaCl₂, 20% NaCl, and 50% KCl situated at (b). Mixture (b) begins to freeze at 530° C., while mixture (a), the lowest freezing mixture of the whole series, begins to freeze at 495° C.

The results of the investigation of the ternary series are somewhat disappointing, because it was hoped that the addition of potassium chloride to the CaCl_2 — NaCl eutectic would effect a considerable lowering of the freezing point, which would have increased the scope of utility of the materials in tempering operations. Nevertheless, it is of considerable interest from the technical point of view to know that the low melting mixtures are prepared from the cheapest materials, because no real advantage is gained by adding 5% of the comparatively expensive potassium chloride in order to obtain a lowering in the freezing point of only 5°C .

40	77.5	12.5	10	565	—
41	32.5	57.5	10	542	—

Allusion has already been made to the disagreement between the results of the present investigation and those of Menge with regard to the existence of the compound $4\text{NaCl}.\text{CaCl}_2$. The formation of such a compound would result in an inflexion in the liquidus not only in the CaCl_2 — NaCl series, but also in the series containing constant but relatively small percentages of potassium chloride, i.e., those series represented by vertical planes cutting the ternary model parallel to the CaCl_2 — NaCl side of the triangle. Such sections show no signs of inflexions, so that for the present the authors are compelled to reject the idea of the formation of any compounds between sodium and calcium chlorides because the whole of the data obtained from the ternary series strongly favour the conclusion that these two salts form a continuous series of solid solutions.

It is hoped to extend these observations to other ternary salt mixtures at some not very distant date.

In conclusion, the authors would take this opportunity of thanking the Birmingham Small Arms Co., Ltd., in whose laboratories this work has been done, for granting the necessary facilities to carry out these investigations.

Meeting held at Birmingham University, on Thursday, November 13, 1919.

MR. L. P. WILSON IN THE CHAIR.

THE MANUFACTURE OF ARTIFICIAL ABRASIVES IN THE ELECTRIC FURNACE.

BY C. J. BROCKBANK.

Artificial abrasives require for their production large quantities of electrical energy, such as can only be furnished cheaply by the enormous water power developments of Canada, the United States, and similar countries abroad. Due to this natural advantage there have developed in Canada several large plants devoted entirely to the manufacture of artificial grinding materials called by various trade names, but consisting of two groups, one silicon carbide, and the other aluminous abrasive, or artificial corundum. The fact that upwards of 140 million pounds of these materials was produced in Canada during the year 1918 shows that the industry has become one of enormous importance. The refractory by-products are also of great importance, and have contributed very materially to increased efficiency in the operation of many types of furnaces. The value of abrasive products exported from the United States alone in the year 1918 was upwards of one million pounds.

Early History.

There are many references in ancient history to the use of abrasives. Emery was mined at the Island of Emiri by the ancient Egyptians during the time of the Pharaohs, and used by them for grinding and polishing those magnificent monuments in existence to-day. The ancient Indian races used a mixture of crushed emery powder and beeswax for polishing stone, and emery and natural corundum constituted the only abrasives of an efficient character in use from those times until silicon carbide (carborundum), the first artificial abrasive, was discovered by Dr. Acheson, in the year 1890.

Unfortunately, silicon carbide cannot be used for all classes of grinding. It is most suitable, and most highly efficient, in the grinding of brittle materials, such as cast-iron, marble, mother-of-pearl and materials of that kind, and the finishing and sueding of leather and so on. It was the attempt of the Carborundum Company to make it a universal grinding material that so nearly led to financial disaster in their early days. The physical properties of silicon carbide render it unsuitable for producing the fine, smooth finish required in steel grinding. It is intensely hard (the next hardest material to the diamond), and very brittle. During grinding the edges of the individual grains are constantly fracturing, exposing fresh cutting edges, which score deeply into a tough material such as steel. Subsequent to the discovery and commercial introduction of silicon carbide, therefore, emery and natural corundum continued to hold their own in a large section of the abrasive field. Unfortunately, the deposits of natural corundum were rapidly exhausted both in Canada and the Southern United States, and the properties of Naxos emery were so uneven that considerable difficulty was experienced in making wheels from it that would meet the diverse conditions and exacting specifications of the steel industry. The discovery that such aluminous ores as bauxite and emery could be electrically smelted with coke, and commercially pure, crystallised artificial corundum obtained therefrom, completed the requirements of the abrasive field and rapidly forced natural emery into the background except for a few restricted operations, such as polishing, particularly the

polishing of glass, for which none of the artificial abrasives is suitable to-day.

The Manufacture of Silicon Carbide.

Silicon carbide is formed by the reaction at high temperatures of silica and carbon. In practice it is found necessary to add varying amounts of sawdust and sodium chloride. Sawdust is used to maintain porosity in the mixture, so that the large volumes of carbon monoxide may escape without causing blowholes at local spots in the furnace; the salt assists in the elimination of the impurities present in the coke and sand as chlorides. A typical furnace mixture when all new materials are used is: Petroleum coke 1500 lb., white sand 2520 lb., sawdust 300 lb. (18 cub. ft.), salt 40 lb. A considerable proportion of the mixture used in a

First stage in formation of silicon carbide. Second stage in formation of silicon carbide. (Crystals forming.)

Surface of silicon carbide crystal. $\times 20$.

furnace is not converted into silicon carbide, acting merely as a heat-insulating blanket, and this material will ordinarily be returned to the mixing department and added in definite proportions to the new materials. Inasmuch as this old mix has lost part of its carbon by oxidation, the proportions are somewhat altered, and a typical operating mixture for continuous use becomes as follows: Petroleum coke 1500 lb., sand 2455 lb., sawdust 300 lb., old mixture, 400 lb., salt, 40 lb. Petroleum coke is the carbon residue left in the stills when distilling crude oils and is the form of carbon that can be used most satisfactorily for producing the highest grade of silicon carbide. This does not appear to be due altogether to its purity, since good silicon carbide cannot be made from lampblack, but is in

some way due to the readiness with which it is converted into graphite by heat. Charcoal is readily changed to graphite, and similarly will make excellent silicon carbide.

Silicon carbide furnaces are built in sizes varying from 1000 h.-p. capacity to 3000 h.-p. capacity. A furnace of less than 1000 h.-p. size cannot be operated economically. A 3000 h.-p. furnace will produce approximately 7% more silicon carbide per unit of power input than a 1000 h.-p. furnace, although the advantage is somewhat offset by the fact that the quality from the largest size is not so good. A 1000 h.-p. furnace is 20 ft. long between the heads carrying the electrodes and 5 or 6 ft. wide inside. The heads carrying the electrodes are 40 in. thick, and two electrodes are used for each terminal, made from graphite 10 in. diam. and 48 in. long. The method of loading the furnace is as follows. The furnace is charged with mixture slightly above the level of the electrodes, and a trench formed in this mixture 36 in. wide and 10 in. deep, which is filled with about 1200 lb. of graphite powder. This forms the resistor core and conducts

Surface of silicon carbide crystal. $\times 20$ diam.

Devitrified layer of quartz in silicon carbide crystal. $\times 20$.

the current from one terminal to the other. The charge is then piled on this core and the furnace is ready to operate.

Power for the plant of the Exolon Co., at Thorold, Ontario, is furnished from the hydro-electric station of the Toronto Power Co. at Niagara Falls. It is three-phase twenty-five-cycle current, and is transmitted to a sub-station adjacent to the abrasive plant at a potential of 60,000 volts. In this sub-station it is transformed down to 12,000 volts, at which voltage it is delivered to the plant.

The furnace transformers used are of the oil-insulated water-cooled type, single-phase, and by means of taps taken off the high-tension side it is

possible to obtain any voltage between 160 and 85. When a furnace is first cut in the highest voltage is used. The furnace should reach full load in less than three hours at this voltage, after which the voltage must be periodically reduced, or the furnace would run overload, due to the negative temperature coefficient of the graphite resistor in the furnace; with a core of the size given, stable conditions should be attained between 85 and 100 volts. Very soon the carbon monoxide evolved will ignite on the outside of the furnace. It is usual to introduce a definite amount of electrical energy and to take off the furnace when that is done. For the size described 22,500 k.w. hrs. is used each furnace run, and the duration of the run will vary from 32 to 34 hours. There is a considerable shrinkage of the mixture during the run, the level gradually falling below the side walls of the furnace. The side walls must not be taken down till at least 24 hours after a furnace has been disconnected; otherwise the product is liable to be injured by oxidation. Subsidiary reactions involving to some degree recrystallisation of the product take place after the furnace is disconnected.

A silicon carbide furnace, efficiently operated, should produce 0.16 lb. of SiC per h.-p. hr., or should require approximately 5 k.w. hrs. for each pound of crystalline silicon carbide. In addition to the crystalline material, one ton of firesand or impure amorphous silicon carbide will be produced per furnace run. This is a very valuable refractory for the lining of brass-melting furnaces, outlasting many firebrick linings, and the demand greatly exceeds the supply, since it can only be produced indirectly as a by-product.

The costs of production have increased greatly since the year 1915, due to the increase in the prices of all raw materials and labour. With power costing \$14 per horse-power year these costs are as follows for the years 1915 and 1918:—

Manufacturing Costs per ton of 2000 lb.

	1915.	1918.
Raw materials	\$19.00	\$40.61
Power	21.82	23.94
Labour	10.51	34.96
Repairs and supplies ...	2.70	5.49
Total manufacturing cost		
(exclusive of overhead)	\$54.06	\$105.00

Finishing of Silicon Carbide.

The crystalline silicon carbide after removal from the furnace is crushed in a pan mill and treated successively with sulphuric acid and caustic soda. This removes the surface impurities from the grain, consisting of graphite, silicon, silicides of iron (mainly SiFe₂), and aluminium silicide. It is then washed, dried in a rotary dryer, and passed over screens which separate the grains into various sizes from $\frac{1}{2}$ in. mesh to $\frac{1}{220}$ in.; finer sizes than this are graded by hydrostatic methods. This material forms the pure product used by the wheel manufacturer for making abrasive wheels. It is mixed with a porcelain bond, and fired in pottery kilns. The process of manufacturing wheels is beyond the scope of this paper.

Aluminous Abrasives or Artificial Corundums.

These are manufactured by smelting a mixture of bauxite and coke in an arc furnace; the impurities, mainly silica and iron oxide, are reduced and settle to the bottom of the furnace, and the fused alumina is recovered in the form of a large pig or ingot weighing 4 to 5 tons. The bauxite used will usually have approximately the composition: SiO₂ 8.40, Al₂O₃ 50.68, Fe₂O₃ 13.22, TiO₂ 2.65,

loss on ignition 24.93. A typical furnace mixture is calcined bauxite 1750, coke 100, iron borings 350 lb. The furnace used is mounted on a water-cooled track and consists merely of a four-sided iron frame with an inner lining of fire-brick. The dimensions will be approximately 5 ft. x 7 ft., and the height of the side walls 5 ft. The hearth is made of pitch and carbon. The furnace is started by placing a layer of mixture about 1 ft. deep in the furnace and laying a train of graphite powder from one electrode to the other on the top of this. As soon as a small path of molten ore is formed this carries the current, and more mixture is charged into the furnace as required.

These furnaces operate at about 100 volts and require 550 k.w. An ingot weighing 4 or 5 tons should be produced with a power input of 18,000 k.w. hrs., but this will vary widely according to the quality of ore being used. When the furnace is full it is removed bodily and a new one inserted in its place.

Reduction must not be carried too far; otherwise the abrasive will be too pure and brittle. The presence of 1–2% of iron oxide, silica, and titanium dioxide increases the toughness of the product. A typical analysis of high-grade abrasive would be Al₂O₃ 97.40, SiO₂ 0.90, Fe₂O₃ 0.32, TiO₂ 1.38%. The metallic residue recovered will contain 10–15% of silicon. Sufficient iron borings are added to the mixture to keep the silicon content of the alloy below 15%; otherwise the material would be too weakly magnetic to be separated from the crushed corundum.

Manufacturing Costs.

During the year 1918 the costs of manufacture were as follows per ton of 2000 lb.: Raw material, \$45.65; electrodes, \$10.82; power, \$7.79; labour, \$19.73; and repairs and supplies, \$6.57; total, \$90.56. It will be noticed that power is a comparatively small proportion of the total manufacturing cost of artificial corundum, and it would therefore seem to be quite practicable that aluminous abrasives should be manufactured in England at a cost that would compete with the foreign product. Important developments in this field are to be expected therefore in the near future.

DISCUSSION.

THE CHAIRMAN asked if the presence of graphite were detrimental to the product as an abrasive; and whether silicon was available commercially for acid-resisting castings, also if its properties were such that it could be worked. He took it from the way in which it was treated that carborundum was resistant to chemical action—both alkaline and acid.

MR. A. E. TUCKER said that if a carborundum wheel were run much below the speed specified it would soon be destroyed, and it was well known that a disc of copper or even of paper had great abrasive action if run at sufficiently high speed. He would like more information about the crystals because they did not appear always to present cutting angles to the work operated on.

MR. F. C. A. H. LANTSBERY asked for further information with regard to the melting of alumina, and also as to the cost involved. What amount of impurities was permissible? Melted pure alumina would probably not be quite so hard as alumina containing a certain amount of impurities. Generally speaking, the addition of impurities, in small quantities, to pure material had first the effect of increasing hardness, more particularly if the impurities went into solution.

Mr. R. A. PAGE enquired whether the electrodes in the furnace melting alumina were vertical or horizontal, as in the carborundum furnace; and also, if three-phase current were used, were two or three electrodes employed?

Mr. J. C. MANN enquired if it were essential that the carbon used should be free from ash or volatile matter; and what was the author's experience of pitch coke?

Dr. H. W. BROWNSDON, referring to the author's suggestion to use "fire sand" mixed with sodium silicate or clay for lining brass furnaces, asked if that was impure carborundum, and what was the price? If the life of such material was ten times greater than that of the ordinary firebrick it could be used fairly freely.

Mr. A. E. TUCKER stated that about three years ago he had obtained for a steel furnace a brick which he had shaped down so as to allow round it about an inch thickness of carborundum. When the other bricks had become worn out the one so treated had remained in first-rate condition.

Mr. BROCKBANK, in reply, said he believed the presence of graphite was decidedly detrimental, particularly for some classes of work. Carborundum, not free from graphite, did not seem to behave well; and to get the best results graphite should be removed from such articles as refractory bricks. The pure silicon casting had not become what he would regard as a commercial success. The cost of such castings was about 5s. per lb.; the few that were provided lasted well. Carborundum was insoluble in acids and alkalis. Filter plates had been made from carborundum which could be used to filter the strongest acids. These were made with 85 lb. of "grain" and 15 lb. of petroleum coke, held together with dextrin or glue and exposed to the vapour of silicon. It was necessary that the crystals should be solid grains of kernel shape; the rougher the better so far as surface texture was concerned. He did not think the precise conditions of successful grinding were understood. The carborundum was harder than the alumina abrasive, but the difference in the properties did not appear to be due to variations in hardness. Alumina abrasives would operate for 20–28 hours, but much depended on the quality of the ore. The difference in properties appeared to be due to the fact that the aluminous products became polished, but particles of the carborundum were continually being broken, exposing fresh cutting edges. The power absorbed varied considerably; there was much waste energy in an alumina furnace, because at times it must simmer. There was the danger of getting a spongy or overburnt material if the energy were forced into the furnace. He found that the toughest alumina abrasive would contain 2% of iron oxide and 2% of titanium dioxide; whether one or the other was responsible for the toughness he could not say. He had never manufactured a material from absolutely pure material; he thought both oxides increased the toughness of melted alumina. The electrodes were vertical; the furnaces were not lined, the mixture forming the lining, and there was a layer about 2 inches thick left when the operation was finished. The outside of the furnace was not water-cooled. Petroleum coke was peculiarly suited for producing carborundum, but pitch coke, if it did not contain too much volatile matter, was quite suitable. "Fire sand" was amorphous carborundum; its price was about £12 per ton.

THE CHAIRMAN, referring to a question as to what was an abrasive, said that a wet cellulose thread was capable of cutting glass under certain conditions when running at a high speed.

Newcastle Section.

Meeting held at Chemical Industry Club, Newcastle, on January 28, 1920.

PROF. P. P. BEDSON IN THE CHAIR.

NOTES ON TUNGSTEN ORE DEPOSITS IN BURMA.

BY J. COGGIN BROWN
(*Geological Survey of India*).

Owing to the constant association in many parts of the world of the natural tungstates of iron and manganese with cassiterite, the common ore of tin, these minerals must have been known to man from a very remote antiquity. It was not until 1781 that Scheele recognised a new acid in the mineral which was later called after him. In 1783 the brothers D'Eluhardt, pupils of Bergman, proved that wolfram also contained tungsten and isolated the new element. The commercial life of tungsten commenced in 1847, when Oxland patented a method for the preparation of sodium tungstate and metallic tungsten. In 1857 Oxland took out another patent for the preparation of alloys of tungsten with iron, steel, and nickel. This was followed in 1859 by Mushet's patented steel, which contained 6–8% of tungsten, 2% of manganese, and a high percentage of carbon. The credit for the more modern development of high-speed steels by heat treatment is said to be due to Taylor and White, who exhibited their products at the Paris exhibition in 1900. About the year 1903 a great demand arose for wolfram, which before that time was regarded as an impurity in tin concentrates; the price began to rise and production to increase, until during the years of the war unprecedented prices were given in uncontrolled countries, and the very ends of the earth were ransacked for supplies.

Tungsten steels are prepared with suitable admixtures of other metals, such as chromium and vanadium. The material used for making the best tools contains 18–20% of tungsten. Such steels are not only exceedingly hard, but they maintain their hardness at high temperatures. As these qualities may be impaired by the presence of small quantities of tin, sulphur, phosphorus, arsenic, bismuth, or copper, all of which occur in nature with tungsten, the necessity for dressing the ores as clean as possible is emphatic.

The introduction of high-speed steel is said to mark one of the greatest advances ever made in the metallurgy of iron and to have completely revolutionised the machine shop practice of the civilised world. An American writer has remarked that to deprive a nation of tungsten is to cripple its military power and its industrial power in times of peace.

The use of tungsten filaments in incandescence electric lamps has also transformed this particular industry, though without conferring any benefit on the producer of tungsten ores, owing to the small quantities used in making millions of lamps. Tungsten steel is also used for making permanent magnets, for the valves of some makes of internal-combustion engines, as contacts for sparking plugs, tremblers, and voltage regulators, for targets and cathodes of Röntgen ray tubes, and in gramophone needles. The metal is a constituent of "stellite," "partinium," and various other alloys. Some of its salts have limited industrial uses.

There are but few natural compounds of tungsten; they are all definitely oxidic in character, and

form a strong contrast to the behaviour of the sulphidic ores. Most of the latter are connected with intrusive rocks of the basic type, but the tungsten ores are usually, if not invariably, associated with strongly acid rocks. The only ores of commercial importance are the tungstates of iron and manganese and of calcium. The iron and manganese tungstates form a striking example of an isomorphous series. The theoretical end products are ferberite (FeWO_4) and hubnerite (MnWO_4), but they have never been found pure. In the absence of chemical analyses it is better to use the term "wolfram" to cover the whole series.

For centuries there has been a small indigenous tin-mining industry in Lower Burma. Thus Ralph Fitch, an English adventurer who travelled there in 1599, has left it on record that he passed "the Iland of Tavi, from whence cometh great store of tinne; which serueth all India." One of the earliest references to the occurrence of wolfram is in a work published by Dr. Mason, an American missionary, in 1846, who states that the tungstate of iron, or wolfram sand, much resembles tin and is found in most neighbourhoods where that ore occurs. He relates how a certain Government officer erected furnaces and tried to smelt wolfram sand under the erroneous impression that he was dealing with cassiterite; but though he tried hard and raised the heat to the highest point he was capable of, the ore still remained refractory and would not turn into tin.

Wolfram was re-discovered in Tavoy by the Geological Survey of India, in 1909, and was first exported in 1910, when about 400 tons was produced. At that time the world's production was about 6000 tons of 60% WO_3 concentrates, and the chief producing countries were the United States, Portugal, and Queensland, with smaller amounts from the Argentine, Bolivia, and New South Wales. By the next year, 1911, wolfram mining was thoroughly established in Tavoy, and an output of over 1300 tons made Burma the leading tungsten-producing country in the world, a position which she maintained easily until 1916, when the boom in the Americas caused both the production of the United States and of Bolivia to exceed hers. In 1914, out of a world's production of some 8000 tons Burma alone produced about 2300 tons. By this time other countries had entered the list—Japan, China, Siam, the Malay States, and Billiton in Asia, the Northern Territory of Australia, Tasmania, New Zealand, and Peru, while the European countries, including Germany and Austria, contributed their small portions.

Although Germany has no important domestic supplies and possessed none in any of her foreign territories, she has been credited with the control, in 1913, of two-thirds of the world's production. Thus she treated nearly 6000 tons of 60% concentrates. The British steel makers generally obtained their supplies of finished tungsten products from the German manufacturers, and it is no secret that August, 1914, found this country with but a few months' stock in hand. It is not within my province to describe the admirable way in which British metallurgists and chemists got the nation out of its difficulties, but I may indicate the manner in which Burma responded to the imperative demand for the raw material. In 1915 all the Imperial supplies were earmarked for the Home Government at a fixed price of 55s. per unit of WO_3 . This was raised in 1917 to 60s. per unit. These prices may be compared with 9s. and 51s., the minimum and maximum prices for the years 1897 to 1914. In Burma itself the Government assisted the miner in every possible way, by importing labour, making roads, and creating a special administrative and technical advisory staff. The mining firms did their best,

and great advances were made in mining and milling methods. As a result, the output increased from 1688 tons in 1913 to 4480 tons in 1917, and from the beginning of the war-year to the end of 1918 no less than 17,636 tons, of a total value of £2,322,000, was exported.

The American output, under the stimulation of an uncontrolled price, which reached a maximum of \$934 a unit, or six times the price offered in the Empire, in 1916 rose to over 5900 metric tons of 60% concentrates, and there was a corresponding increase in all other producing countries, so that the world's production of about 8000 tons in 1914, rose to 12,000 in 1915, 23,000 in 1916, 28,000 in 1917, and 35,000 in 1918. In 1917, China, which had been an insignificant producer before that time, brought 1500 tons into the market, rising in 1918 to over 10,000 tons, or more than the whole world's production for any one year before 1915.

In 1918 92% of the world's tungsten ores came from the mountains bordering the shores of the Pacific Ocean, 5% from the Iberian Peninsula, and 3% from England, Germany, and other European countries.

Tungsten ores are almost invariably associated with the more siliceous granite rocks, and the most important metallogenic province is the Sino-Malayan one, which includes Burma and the Shan States, the Malay States, the Dutch East Indies, Siam, Tongkin, and South China. The deposits of Japan and Korea may represent an extension of this province.

Wolfram and cassiterite have been found at intervals over a distance of 750 miles in Burma, always in direct association with the great granite ranges which stretch from an unknown termination in the Shan States to the extreme south of the province. The isolated occurrences of the Kyaukse, Yamethin, Karreni, Thaton, Amherst, Tavoy, and Mergui districts are links in a chain which forms the northern extension of the Indo-Malayan mountain system, and which continues south through Lower Siam and the Malay States to Banca and Billiton, forming the core of the Peninsula, and carrying its distinctive metallogenic characteristics throughout its entire length.

The geological history and structure of Tavoy, the most important mining field of Lower Burma, are simple. A series of very old sedimentary rocks in which clay slates predominate, was intruded at an unknown period by a white, very siliceous granite, which is now exposed where denudation has removed its earlier covering. The ores of tungsten and tin are always found in or near the outer margins of the granite intrusions.

Both wolfram and cassiterite occur in Tavoy as segregation deposits in the granite itself, in pegmatite veins, and in quartz veins which penetrate the granite or the sedimentary rocks. Other minerals that may occur in the veins are mica, fluorite, molybdenite, pyrite, chalcopyrite, pyrrhotite, arsenopyrite, galena, zinc blende, native bismuth, bismuthinite, and, in one case, topaz. Both minerals occur in greisens, the bands of altered granite adjoining the veins themselves, and in residual, detrital and talus deposits of the slopes. Cassiterite is transported and found in river gravels and other alluvial deposits. Wolfram is not.

It is stated in text-books that the Tavoyan field is characterised by the universal presence of tourmaline, and that columbite is a common mineral in it. Both these statements are incorrect.

Every granite intrusion in Tavoy has its associated ore-bearing veins in some part or other, though large expanses of granite are found also which do not contain veins. This is either due to the fact that veins were not formed there originally or have been cut away by denudation at a later period.

Every producing mine is situated on or near the granite contact. The veins themselves vary a great deal, yet they possess certain generic features which may be classified as follows:—(a) They are formed by the filling of fissures; (b) they often occur in parallel groups; (c) they often form a series of overlapping lenses; (d) the lenses themselves are irregular, they thin out and thicken again, or split up and reunite; (e) they generally possess clean and well-defined walls; (f) alteration of the granite walls to greisen is universal; (g) the vein quartz is dense, milky white and very compact; (h) mica is invariably present and sulphides very often; (i) secondary movements of the fissures are common.

The veins are of all sizes and lengths, from small stringers to well-developed individuals which can be traced for miles. The undergrowth of the forests and the thick soil cap make it difficult to follow the veins, but several are known over a length of 1200 feet. Both wolfram and cassiterite have a tendency to deposit in little quartz veinlets half an inch or more in thickness, and when these are in close association, and especially if the ground is soft, and can be broken down by water under pressure, valuable sources of the ores are formed. Most of the veins strike in the same direction as their parent granite masses, that is north and south to north-west and south-east. Dips are usually very high. The mica of the veins occurs in small flakes, and muscovite is the commonest variety. Green chlorite is also found, and a lithium-bearing chlorite has been reported. Wolfram and cassiterite have a very erratic distribution in the veins. In extreme cases great slugs of wolfram up to a ton in weight have been exposed, but any profit which comes to the miner therefrom is usually lost in driving through barren ground to find the next one. This irregular distribution, coupled with a pernicious local system of mining, makes the exact valuation of the veins a very difficult matter. Contents varying from 1 to 3% are recorded, and in most cases are probably underestimated. No mining has yet been carried on in Tavoy below about 400 feet from the granite contact, but a study of all the available evidence leads to the conclusion that there is not much likelihood of wolfram giving out as greater depths are attained in most of the larger mines. In my opinion the question of the permanence of wolfram in depth is of secondary importance to that of devising means of mining narrow veins in hard granite, and of recovering the mineral content by modern methods with the poor labour supply available.

The order of deposition of the metallic minerals is a subject which has evoked much discussion, as it follows that if cassiterite was deposited at a higher temperature than wolfram there is a possibility of wolfram giving place to tin ore at depth, and of the field becoming a large tin producer, like the Federated Malay States further south. Theoretical speculations on geochemical processes, which are impossible of reproduction in the laboratory by any means at our disposal to-day, may be put aside. Field evidence is convincing that molybdenite was the first ore mineral to form, that it was followed by wolfram, and it, in its turn, by cassiterite, for hundreds of specimens occur in which cassiterite was clearly secondary to wolfram in cases of mixed growths.

Although it is possible to imagine theoretical conditions under which tungsten ores in the upper part of a vein might be dissolved to form solutions, which percolating downwards should have their tungsten contents precipitated in a lower horizon, the fact remains that in Burma there are no zones of any economic importance in wolfram mines which have been enriched by solution and reprecipitation in any way comparable to those, say, of copper and silver, in other parts of the

world. Tungsten solutions are very easily precipitated by ferric salts, but this precipitate is colloidal and difficult to filter. It is doubtful if it would lodge in a definite deposit. Ferric tungstate and the hydrated oxide, natural tungstic acid, are in any case compounds which it is impossible to recover by ordinary concentrating devices.

The relative proportions of cassiterite and wolfram in the concentrates vary a great deal from mine to mine. The tin content in vein material is higher in granite veins than in those of the sedimentary rocks. Concentrates which are practically tin free only occur in a few cases, and the veins from which they are derived are all in argillites or clay slates. Concentrates from surface deposits are always richer in tin ore than those from veins. The best Tavoy concentrates contain over 70% of WO_3 , and all the separated material contains between 65% and 70%. A calculation based on the probable composition of the concentrates produced from 50 mines in 1918 showed that as produced the total bulk averaged 55% of WO_3 , and 15% of metallic tin. These mines produced over 95% of the district's total in that year.

Mining methods of the early days were of a very primitive character, and the industry still suffers because they have never been entirely eradicated. The first discoveries were made by Burmans and Karens, who collected the ores from the outcrops. They were speedily followed by Chinese immigrants, whose "crude methods exasperate equally with their bland unwillingness to improve on them." A gang of Chinese works under a contractor, who is paid according to the amount of clean, high-grade concentrate he brings in, and usually a footage rate for underground operations as well. In many cases the Chinese miner was allowed to work as he pleased, with the result that vein workings became rabbit warrens and valuable surface deposits were buried under débris. Ore concentration methods were of the crudest kind, the wolfram-bearing quartz being crushed by hammers on a flat stone and the powdered stuff washed up in a cradle or pan. The whole sequence of operations was extremely wasteful. Low-grade ore was left underground or thrown away on scattered dumps, while the losses in crushing and dressing were very high. Of late years there has been a change for the better. Tributing is still widely practised, but it is controlled to a degree hitherto unknown; deep level exploratory work is now carried on by the aid of machine drills driven by compressed air; concentrating mills have been designed and erected; large-scale mine plans and sections are required by the mining laws.

Wolfram is a difficult mineral to recover even by the most modern devices. It possesses a perfect cleavage and breaks down into thin, mica-like plates when it is powdered. By the action of stamps these naturally become slimed, and this leads to heavy loss. It appears to me to be better to adopt the practice in which a minimum amount of fine material is produced, and I am of the opinion that a concentration system which makes full use of hand picking, coarse crushing in rolls, sizing, and jigging, with the removal of wolfram and cassiterite at every stage where they can be obtained as coarse as possible, followed by full use of present practice as regards the inevitable fine-ground material, is preferable to the earlier one in which the unsorted ores were taken direct from the mine to stamps and reduced to the consistency of tooth powder before any attempt was made to separate their valuable contents.

In a climate like the Tavoyan one, which has a monsoon rainfall of 200 inches or more, the quartz veins undergo rapid denudation and shed their contents into the surface soil. Valuable deposits are thus formed containing wolfram and tin ore in

the surface covers of the hill sides, and of tin-stone alone in the true water-sorted alluvium of the valleys. The greater part of the output is still derived from these. In the first stages of a mine's history the beds and banks of the stream are cleaned up. Then water is led by ditches or flumes on to the profitable ground which lies at higher levels. Most of the larger mines are supplied with water brought by elaborate systems, often from considerable distances. If a gravity supply is not available, water is lifted by pumping, provided the area and value of the bearing-ground warrant the cost. Occasionally rich residual deposits are excavated by hand and treated in a pan similar to those used in washing gem gravels at the Burma ruby mines or the Kimberley diamond fields. It is claimed that the pan saves a larger proportion of fines and does the work with about a third of the water required in hand working with an ordinary sluice box. When the rich ground is buried under overburden it is often broken down and washed in one operation; for this purpose monitors or hydraulic giants are used, the ores being recovered in sluice boxes in the usual way. Hydraulic elevators become necessary when the tailings can no longer be disposed of by gravitation, or gravel pumps are used instead of the elevator by reason of their greater efficiency. In the most advanced installations of this kind, when the water can be obtained from a source very much higher than is necessary for hydraulicizing, it may be used to drive a nozzle pump by means of a Pelton wheel, or the whole system may be electrified by its means, as is done at the Kanbank mine, where the same water is used repeatedly for hydraulicizing and the pumps are mounted on a barge which can be floated nearer to the working surface as it recedes.

Previous to 1916 the mixed concentrates were shipped as they came from the mines. In that year a magnetic separating plant was installed by the High-Speed Steel Alloys Mining Co., Ltd., so that a portion of the output is now separated before export. The machines used are of the Ulrich type.

Very erroneous ideas are prevalent in literature regarding the behaviour of the natural tungstates when exposed to the action of air and water. Thus, W. H. Emmons classifies tin and tungsten together with gold (in part), bismuth, chromium, and molybdenum. Again, R. H. Rastall writes:—"The outstanding feature of the tungsten minerals is their great stability and resistance to any kind of chemical or mechanical alteration. . . . They are specially liable to occur in placers and other forms of transported deposits. . . . In this respect both wolfram and scheelite behave like stream tin, gold, and platinum." If the word "placer" means stream-borne and water-sorted alluvium, then there are no wolfram-bearing placers in Burma. Wolfram may occur at the foot of slopes, where the detrital deposits of the hill sides merge into the true placers of the valley bottoms, but long before the clays, sands, and gravel deposits have been sorted out and transported by running water the wolfram has disappeared, though it comes from the same veins as the tin ore which remains. The rapidity with which wolfram decomposes in the surface soil is very remarkable, and is accounted for by its cleavage, resulting in its disintegration on movement with the production of a comminuted form eminently suited for chemical decomposition. Wolfram is readily leached from the outcrops of veins. The ready oxidation of its sulphide associates yields acid solutions which attack the mineral until nothing is left but cindery oxides of iron and manganese or a bloom of tungstic acid in the spaces once occupied by the crystals. R. W. Gannett has carried out laboratory experiments to determine the effect of various solutions such as are found

in ground water on tungsten minerals, and to determine what natural reagents precipitate it from solutions. He concludes that tungsten minerals are somewhat soluble. The field evidence in Burma undoubtedly supports this conclusion. In this connection I would point out that the natural sulphides of molybdenum and bismuth are also leached, dissolved and oxidised away in their passage from a vein through a soil cap towards the valley deposits in tropical countries.

All observers are agreed that the wolfram, cassiterite, scheelite, and associated minerals emanated in some form or other from the original molten granite, but there are differences of opinion as to the manner in which they were collected and then deposited in the veins where they are now found. It is generally admitted that after the crystallisation of the main mass of the granite a watery and highly acid mother liquor was left in which the tungsten and tin compounds were dissolved. Whether this mother liquor derived its water from the original magma, or from some external source is a matter of speculation, as also is the part taken by mineralising gases in the operations. The facts on which we have to build our theories are these: that tourmaline, which would indicate the presence of both fluorine and boron, is absent; that calcium fluoride is a widely-distributed accessory mineral; that sulphides of various elements are common and persistent; that wolfram and cassiterite occur in pegmatites; and that some of the pegmatites can be observed passing laterally into quartz veins of the ordinary type carrying the minerals. The presence of fluoride and the fact that both tin and tungsten form highly volatile compounds with fluorine, coupled with Daubree's synthesis of cassiterite by the action of water on tin fluoride, are used by the advocates of the pneumatolytic hypothesis in support of their views.

Whatever the inner details of the processes may have been, it seems certain that the mineral veins appeared as a direct result of fractional crystallisation, through a series of varying phases, induced in the original magma by decreasing temperature.

DISCUSSION.

Mr. F. H. SHARPE said that tourmaline was present in all Australian ores he had handled. He asked if the author had any theory as to the origin of bismuth; he had specimens which suggested that a sort of transmutation had taken place. It was interesting to observe the similarity which existed in Australian and Burmese ores.

Dr. H. PEILE said that figures regarding the cost of mining etc. would be very useful. The future depended on a regular supply at a low cost.

Mr. W. JONES said that in Portugal exactly the same characteristics occurred as in Burma. In Portugal, as in Burma, the wolfram invariably existed at the contact of the Silurian schist and granite. In his opinion the geological maps of Portugal were the best in the world so far as exact information was concerned. What was the average percentage of concentrates in Burma? He considered a mine giving one ton of tungsten concentrates from each 100 tons of quartz was a good mine, and it was difficult to get a higher yield than that. Sometimes mines gave 3 or 4%, but they were soon worked out. His experience, not only in Portugal, but in Bolivia and the Argentine, was that mining tungsten was the most difficult of mining operations. In those areas he had never seen decomposition on such a large scale as Mr. Brown had mentioned, but he supposed it was due to the climatic conditions and the acidity of the soils. So far as tungsten was concerned there was no need to fear American competition. The Americans were considering the advisability of imposing a duty of one dollar a pound on our tungsten products.

Dr. J. H. PATERSON referred to the progress made in machine tool practice owing to the adoption of high-speed steel.

Mr. COGGIN BROWN, replying to the discussion, said that he recognised that most of the wolfram of the world was associated with tourmaline, a fact

which made its absence in the Tavoy field all the more remarkable. He could advance no particular theory on the presence of bismuth, but thought it belonged to a later epoch. Costs of production in normal years could not be judged from war-time conditions; besides, it was impossible to lay down a general figure over such a large area as Burma, especially as the system of working varied greatly on different mines. The cheapest wolfram was that obtained by hydraulic surface deposits. There were mines which had made large profits in the past when the value of wolfram was much below 55s. per unit of WO_3 . He had already mentioned the difficulties of valuation, and that contents varying from 1 to 3% of concentrates had been recorded and were probably underestimates. The only way to arrive at a correct valuation in vein deposits with scattered values of this sort was, in his opinion, by large-scale stoping tests, and the field as a whole had not advanced to that stage yet. Some of the mining engineers of the district adopted a minimum of 1.5% recovery in their calculations, and he thought that that was a fairly safe figure.

A CONSIDERATION OF SOME FACTORS AFFECTING THE OXYGEN ABSORPTION OF LINSEED OIL.

BY A. DE WAELE, A.I.C.

The literature on the subject of the oxygen absorption of linseed oil is very rich, the earlier experimenters (Livache, Bishop, Hübl, Lippert, etc.), however, interpreting what is more correctly expressed as increases in weight of the oil on exposure as oxygen absorption or oxygen values. I have already dealt with the incorrectness of this view (de Waele, *Chemical World*, 1914, 3, 11, 300) and given a criticism and résumé of the work of the later experimenters (Weger, Genthe, Krumphaar, and Wilson and Heaven), whose results on theoretical grounds may be considered as approximating more closely to the true oxygen absorption.

A tentative view is held in some technical circles as to the differences in mechanism in the process of oxidation resulting from the use of different driers. An extension of this hypothesis is to the effect that lead and manganese, as driers, perform their catalytic functions in different ways according as to whether the oxidation takes place in a dry or a damp atmosphere.

In consequence of indications that atmospheric conditions appeared to be responsible for variations in the properties of the oxidation products of linseed oil in large-scale practice in linoleum manufacture, some experiments were carried out in which the variation in weight of linseed oil on exposure were considered in relation to the humidity of the surrounding atmosphere. The atmospheric conditions are capable of resolution into two factors: the actual proportion of moisture present, which would be given by the pressure of water vapour, and the relative saturation, i.e., the percentage of moisture present on the maximum amount at saturation.

Since linseed oil on exposure to air not only takes up oxygen, but loses some as volatile products, it is reasonable to suppose that equilibrium conditions of the oxidised product with the surrounding atmosphere will be to some extent determined by the actual proportion of decomposition products present in the latter. Thus, at the point

(5) The relative stability of polymerised oil is clearly shown both by the continual upward tendency of the curve and by the closeness of the ordinates shown at the 33rd and 133rd day periods.

(6) For the period considered it is interesting to note that the more rapidly oxidisable unpolymerised oils (lead and lead-manganese) do not ultimately show such a rapid decomposition (as shown by a fall in the end of the curve) as the less rapidly oxidised oils (unsiccated and manganese oils). The polymerising effect of lead drier (R. S. Morrell; Chem. Soc. Trans., 1918, 113) with production of weak ring formation may be the cause of this.

The influence of moisture on the variations in weight may also be considered in the light of the conclusions reached by Gardner (Circular No. 70, Paint Manufacturers' Assoc. of the U.S.; this J., 1919, 832A), in which the first decrease following on the initial increase due to partial saturation by oxygen is assumed to be due to the evolution of volatile decomposition products of the oxidised glyceride, the second increase being due to decomposition of the glyceride into fatty acids and glyceryl radicle, which latter would then absorb water to form glycerol with increase in weight. The second decrease in weight would then be due to decomposition of glycerol to formic acid etc. The present writer is, however, of the opinion that the liberation of free fatty acid on oxidation is improbable, the high acid values observed in oxidised oils being more probably due to groupings which under suitable conditions of hydrolysis, such as in neutralisation, would function as carboxyl or hydroxyl groups. Such hydroxyl groups attached to ring nuclei formed by inner polymerisation subsequent to oxidation would function in the same way as phenolic hydroxyl groups, the existence of which are, strongly indicated by the high acetyl values of oxidised oils.

ESTIMATION OF PARAFFINS IN COMMERCIAL TOLUOL.

BY E. LEWIS.

With reference to the paper by Mr. H. G. Evans under the above title (this J., Dec. 15, 1919, 402 T), attention may be drawn to a method which was in use in a number of T.N.T. factories during war time.

The determination was actually carried out on the mononitrotoluol and the paraffin content calculated on the original toluol. One litre of mononitrotoluol was subjected to fractional distillation using a three-section Young's evaporator column, collecting that portion which distilled below 160° C. The distillate consisted of a small quantity of mononitrotoluene, together with the whole of the un-nitrated toluene and paraffins. Extraction with 90% sulphuric acid removed the nitrotoluene and sulphonation with 20% oleum and subsequent extraction with 90% sulphuric acid removed the toluene, the residue being the paraffins, which were weighed and a solubility correction applied.

This method avoids the sulphonation of a large volume of toluol, a reaction which is difficult to regulate. The un-nitrated toluol may also be determined by weighing before and after sulphonation. It may be of interest to note in this connection

that during an investigation of the composition of toluol supplied by The Gas Light and Coke Co., Beekton, it was found that the paraffin present consisted almost entirely of isomeric octanes, which in spite of surviving the initial nitrations were decomposed during the more vigorous, final nitration of the toluol into trinitrotoluol.

ESTIMATION OF PARAFFINS IN COMMERCIAL TOLUOL.

BY H. G. COLMAN.

The method described above by Mr. Lewis, whilst probably giving a fairly accurate estimation of the percentage of true paraffin hydrocarbons of the C_nH_{2n+2} series in commercial toluol, does not give a correct figure of the total percentage of saturated aliphatic hydrocarbons in the original toluol. These consist not only of true paraffins, but also to a considerable extent of cyclo-paraffins, which last are to a very material extent attacked and removed both in the original nitration of the toluol and in the subsequent treatment with 20% oleum prescribed by Mr. Lewis.

A RAPID METHOD OF ESTIMATING WATER IN CRUDE CAMPHOR.

BY K. W. LANE, B.A., AND O. F. LUBATTI, DR. CHEM.

The following method has been devised for the rapid estimation of water in crude camphor. Five grms. of the crude sample (in the form in which it was received, "coarse, granular fragments") is placed in a centrifuge tube having a barrel of 25 mm. and a narrow tube of 4 mm. internal diameter, the latter being sealed at the lower end and graduated. In shape it resembles the central portion of a pipette. Resting on the coned junction between the narrow and wider tubes is a small 60° funnel-support of nickel wire gauze, on which, before the introduction of the camphor, is placed a piece of cotton-wool sufficiently large to act as a filter. Thirty c.c. of benzene, which has been saturated with water at laboratory temperature and centrifuged in a suitable vessel before separating the water in a separating funnel, is introduced into the tube, which is then placed in a suitably shaped wooden holder and introduced, balanced by a second similarly treated tube, into a centrifugal machine. After running the centrifuge for a couple of minutes the water in the sample is found in the narrow tube, the insoluble impurities being retained by the cotton wool. The narrow tube, which is calibrated by running in small volumes of water from a burette with a fine point and etching with hydrofluoric acid, gives the percentage of water direct. Any particles of water which may have been retained mechanically by the wool or walls of the tube are disturbed by careful stirring with a glass rod, the tube is re-centrifuged, and a second reading taken. When stirring gives no further increase in the volume of the water in the narrow tube the separation is considered to be complete. In the case of unusually pure samples, the gauze filter may be dispensed with. Using this method, it has been found that constant readings are given by the same sample, and that the addition of a known volume of water to the experimental tube produces, after centrifuging, the theoretical increase of the reading in the narrow tube, showing that there is no appreciable retention of water by the filter.

MIR. JULIAN L. BAKER IN THE CHAIR.

THE THEORY AND PRACTICE OF LUBRICATION: THE "GERM" PROCESS.

BY HENRY M. WELLS AND JAMES E. SOUTHCORBE, M.Sc.

The considerations which we wish to bring forward in this paper are the results of many years' experience of the problems of lubricating oil and lubrication, studied from a physical and physico-chemical standpoint, assisted by an intimate and daily contact with the lubrication of all types of machinery and prime movers. Our primary object was to elucidate the reason for the obviously superior lubricating efficiency of fatty glycerides over "straight" mineral oils in a large number of practical cases which had come to our notice.

As a corollary to this we had to review the physical principles upon which lubrication depends and to seek an explanation of the peculiar property which has been called "oiliness," "body," etc., by authorities in the past.

It may not be out of place here to review the position of our knowledge of lubricants and lubrication.

Professor C. V. Boys, in his Presidential address to the Physical Society in 1908, crystallised the position very happily in these words:—

"It was found that the lubricating property of oil depended on something which at present is unknown—It is not viscosity—animal and vegetable oils lubricate better, i.e., they are more 'slippery' than mineral oils of the same viscosity, and though the oil trade has known how to make good 'slippery' mixtures, no one at present knows what 'oiliness' is, and this is at the present time an important physical quest of the engineer."

Again, Professor J. S. Brame has said that "the property of 'oiliness' was one of the most puzzling of the properties of oils. By some it was regarded as unnecessary to connect it with viscosity directly, since it was possessed in a much greater degree by some fixed oils than by many mineral oils which had practically the same viscosity."

It is necessary to distinguish clearly between two distinct classes of lubricating practice. On the one hand we have the lubrication of fast-moving shafts etc. supplied with a large excess of oil frequently under pressure, and in this case the frictional values are dependent primarily upon the viscosity of the oil; the mathematical and experimental investigation of these cases have been amply treated by Reynolds, Tower, Lasche, and others. On the other hand we have to deal with slow speeds at high bearing-pressures, frequently with a very limited supply of oil, and it is in these cases that the special property of "oiliness" or "body" is requisite to maintain the film, and it is here that viscosity measurements no longer assist us in the choice of the lubricant.

This view received unanimous support at the recent discussion on lubrication at the Physical Society.

What are the possible physical properties of a liquid which influence its character as a lubricant? They are viscosity, density, capillarity or surface tension, compressibility, and tensile strength. It is true that very little work has been done on compressibility and tensile strength, but from the observations of Worthington and others it would appear doubtful whether they would play a *distinguishing* rôle in the differentiation of oils; and, further, as we shall point out, there is what appears to us an adequate explanation of the nature of oiliness without calling upon these properties.

So far as density is concerned there exists a wide range of petroleum mineral oils possessing specific gravities identical with those of the fatty or fixed oils, hence it is clear that density plays no determining part. Viscosity is, of course, of great significance in the cases of high speed etc. just referred to.

Now it remained for Ubbelohde to point out that only a liquid which "wets" or "spreads over" the solid can constitute a true lubricant, because in order for the liquid to force itself into the narrower spaces of higher pressure it is essential on capillary grounds that the said liquid shall "wet" the solid surfaces.

Consider the case of two eccentric glass surfaces which are being forced together with a drop of mercury or oil between them. Now since the mercury (fig. 1) does not "wet" or spread over the glass, the meniscus in this case will be convex to the liquid, while in the case of the oil (fig. 2), which wets the surfaces, the meniscus will be concave.

FIG. 1.

FIG. 2.

In the case of fig. 1 (mercury) the tendency on capillary grounds will be for the liquid to gather itself up into a drop and to pull the liquid film in the direction of *a* away from the narrower restricted area of greater pressure at *b*. In the case of oil (fig. 2.) the opposite will be the case. The oil will, owing to its meniscus, tend to be pulled towards *b* or, in other words, will force itself into the narrow spaces.

This is exactly what is required in a lubricant, namely, that it shall penetrate into the narrow spaces between journal and bearing, and from the above considerations one clearly sees that liquids which do not "wet" solid surfaces cannot be described as lubricants.

Only those liquids which "wet" a solid surface possess lubricating power in the generally accepted sense.

Although these considerations appeared to indicate the connection between lubrication and capillarity, it will be seen that they only go so far as to enable us to say that mercury is not a lubricant and that oil is a lubricant. This is a conclusion of considerable theoretical interest, but it is not very

helpful to the oil technologist who desires to differentiate between different classes of oils.

Accordingly we find that these speculations of Ubbelohde led to no practical result.

On the other hand, certain theoretical considerations had led to the conclusion that the permanence of liquid films depended upon capillary relationships, and in particular that *pure liquids would not form stable films*. These principles had not been applied, however, to the problem of lubrication, and, in fact, they were directly contradicted by prevailing practice in which there was a constant tendency towards greater purity, *i.e.*, in the direction of refining the mineral oils which were used, and in the direction of using acid-free oil as a compounding ingredient.

The generally accepted view was therefore that capillarity was not a deciding factor in connection with the phenomenon of "oiliness," and various standard works contain statements to this effect.

It was under these conditions that we began our experiments. We were at once met by the fact that it was not possible to measure the surface tension between oil and the solid metal bearing, and it is probably on this account that Ubbelohde's speculations remained abortive. The usual "surface tension" is that of oil against air, and we confirmed the results of previous investigators, *viz.*, that the results so obtained, for instance, by observing the rise in a capillary tube, shed no light at all on the question under consideration.

At this point we decided to measure the surface tension of the oil against an immiscible liquid in the hope that this might furnish some criterion of "oiliness." On proceeding to measure this interfacial tension, *i.e.*, the surface tension between oil and water, startling results were at once obtained. The method of experiment was by the drop pipette as follows:—The pipette consists of a U-shaped capillary tube provided with a bulb A and a ground glass orifice B. The bulb A is filled with oil to the mark E. By means of the capillary D a very slow flow of oil may be obtained at B by opening the stop-cock C. The orifice is immersed in a beaker of water, and the number of drops formed by the given volume of oil in A is counted. The surface tension oil-water is inversely proportional to the number of drops.*

A series of mineral oils were tested with this instrument, and then a series of animal and vegetable oils and compounded oils.

The following table shows a few results selected from a very large number of trials:—

Table of Interfacial Tension by Drop Numbers of Various Oils Against Water.

OIL.	Mean temperature 70° F.		Tension in arbitrary units.	
	No. of drops at constant orifice and head.			
Paraffinum liquidum	95	100		
0-905 mineral	101	94		Mineral oils.
Solar red mineral	102	95		
Non-viscous neutral	99	93		
Olive	132	72		
Rape	138	68		Fatty oils.
Coconut	161	59		
Lard oil	128	73		

A glance at the table shows the surprising fact that *the interfacial tension against water of the vegetable and animal oils is much lower than in the case of a mineral oil.*

What is more, we were struck by the fact that we had here a test which showed a distinct physical difference between mineral and saponifiable oils independent of viscosity, density, etc., and this difference appeared to be in conformity with the lubricating properties of the oils.

It now remained to enquire what was the reason for the difference in tension. After considerable experimentation we proved that the lowering of the interfacial tension against water in the case of fatty oils was due to their slight content of free fatty acidity.

The following table shows some of the results:—

OIL.	Free fatty acids, calc. as oleic.	Drop no.	Interfacial tension.
0-905 mineral	nil	101	100
98% mineral	1-9	125	80
2% com. fatty acids			
97% mineral	2-8	130	78
3% com. fatty acids			
Olive	2-2	125	80
Olive	4-5	140	72
Rape	2-5	132	76
Coconut	4-1	148	68
Olive (neutral)	0-1	110	92
Rape (neutral)	0-15	108	93

By removing the free fatty acids from the saponifiable oils the tension rises, and by adding free fatty acids to the mineral oil the tension can be lowered.

Now, all commercial animal and vegetable oils contain small quantities of free fatty acids, and even if the utmost care has been taken in refining to remove the acidity, hydrolysis soon sets in and free acids are formed which, in even relatively minute quantity, suffice to lower the surface tension.

The following table shows the percentage of free fatty acids in representative samples of animal, vegetable, and compounded oils on the market:—

	Acidity (as oleic).
Animal oil, pale	4-2 to 25-55
" " brown	12-02 to 30-32
Castor, firsts	0-49 to 1-70
" seconds	2-12 to 7-40
Coconut, Cochio	1-26 to 19-11
Colza, Belgian	1-97 to 3-22
" Stettin	1-41 to 4-48
Lard, pressed	0-28 to 0-71
Olive oil, Algerian	2-52 to 13-72
" Gallipoli	12 to 33-14
Palm oil	24-68 to 56-05
" bleached	14-1 to 27-49
Rape oil, Black Sea, refined	1-82 to 4-34
" East India	1-26 to 4-24
Sperm oil, Arctic no. 1	0-56
" " no. 2	0-42 to 4-34
" Southern	0-7 to 2-86
Tallow	1-55 to 43-71
Standard Brands of Compound Oils on the Market.	
	Acidity (as oleic).
Marine engine oil, D	1-3%
" " " O	5-15%
" " " T	4-5%
Motor oil, X	0-26%
" " Y	0-5%
" " Z	2-5%
Compound steam cylinder	0-4%
Medium gas and oil engine oil	0-25%
	0-38%
Light gas and oil engine oil	1-6%
	1-3%
Heavy gas engine oil	1-28%
	2-5%
Oil engine oil	0-7%

The above table is representative of the general glycerides and commercial compounded lubricating oils in daily use on all types of power plant, and we see that fatty acids are always present to a certain extent. From the foregoing it is demonstrable that:—

1. Capillary effects (hitherto ignored in lubrication) play a fundamental part.

* Donnan, Zeit., f. Physik. Chem. vol. 31, etc.

2. The presence of fatty acids in an oil lowers the surface tension of said oil against water.

3. A neutral glyceride possesses a similar tension to a neutral mineral oil.

4. The addition of a relatively minute amount of a fatty acid to a neutral mineral oil reduces the tension to that of a commercial animal or vegetable oil or compounded lubricating oil.

Now it remains to enquire how far these results influence the theory and practice of lubrication of solid surfaces. It might be argued that the interface between oil and water is a different thing from the interface between oil and metal, and that the conclusions drawn from the one case are not necessarily applicable to the other. As a matter of fact such similarity in effect is not unknown in other instances, and to obtain more conclusive evidence Professor Lewis has measured the interfacial tension between oil and a liquid metal—mercury. (It should not be forgotten that solid-liquid interfacial tension cannot be measured.) His results are as follows:—Pure neutral mineral oil, 100; same mineral oil plus 2% of commercial fatty acid, 89. It is seen that again there is a lowering in the interfacial tension as a result of the addition of the organic acids, and, what is more striking, the relative lowering produced is very much the same as it is in the case of an oil-water interface.

Professor Lewis remarks:—"One may conclude therefore with some confidence that the addition of the organic acids will lower the tension at any metal-oil interface."

Again, as already pointed out, the permanency of films is dependent upon a diminished interfacial tension between the oil and the metal in contact therewith. If such a film is broken the possibility of its uniting again to form an unbroken layer depends entirely upon the interfacial tension being low. Any substance which lowers the interfacial tension causes the liquid to spread over a larger area of the solid. It follows therefore that if a substance be added to an oil which brings about a lowering of interfacial tension, such addition will act favourably as far as lubrication is concerned by preventing a rupture of the liquid film and preventing in turn the metals coming into direct contact.

The capacity for spreading may be considered as partly physical and partly chemical, due presumably to residual valency. The effect is to render the transition layer between the liquid and solid less abrupt. This diminution in abruptness can be brought about by chemical action direct or indirect across the transition layer or by the solubility of some third substance in both phases.

H. S. Allen has recently pointed out that on Langmuir's view oiliness depends on the chemical forces called into play between the active part of the oil molecule and the solid surfaces of the bearing.

Now it is obvious that there is a tendency for chemical activity between the metallic surfaces of bearing and journal and an oil containing free fatty acidity, while such tendencies are less pronounced in the case of a neutral mineral oil. Such a tendency would render the transition between oil and solid surfaces less abrupt, would manifest itself by reduced interfacial tension, and would result in better spreading and consequent increased efficiency in lubrication.

There is little doubt in our minds that the physical rationale of the property of "oiliness" is now explained, and we have confined ourselves so far to a statement of the physico-chemical experiments which we have made and to the development of the physical theory.

Conclusive as it appears to us we have proceeded to test and verify the conclusions by direct friction measurements, and finally by the only real touchstone, namely, the test of experience in a long series of practical trials on all types of machinery and prime movers of the very largest sizes.

We will proceed to consider some of the results in detail.

First we beg to tender our thanks to Mr. L. Archbutt for the frictional test made by him, which he has communicated to the Physical Society at its recent discussion on Lubrication.

Archbutt has made a series of determinations of the frictional coefficient on a Thurston machine under a load of 270 lb. per sq. in. at the very slow speed of 7 ft. per minute.

His results are as follows:—Pure mineral oil, 0.0017; do. plus 1% rape oil fatty acids, 0.0033. He finds that 1% of free fatty acids lowers the coefficient as much as does 60% of pure rape oil (acid-free).

These results have been confirmed by us on an independent machine, as we shall show later.

He has also shown, however, that pure neutral rape oil also possesses a lower coefficient than mineral, and concludes that "these results would suggest that the oiliness or lubricating efficiency of the unsaturated molecules of rape oil was really as great as that of the free fatty acid molecules, but that the acid molecules were much more active in their influence on the hydrocarbon molecules of the mineral oil."

These results, which show that 1% of free fatty acids of rape oil added to a mineral oil are as effective in reducing the value of the frictional coefficient as is the addition to the mineral oil of 60% of neutral rape, are striking confirmation of the above described principles, and coming from a totally independent and unbiassed experimenter afford great support to our contention that it is not the glyceride but free fatty acids in a compounded oil which improves its lubricating value.

Through the courtesy of one of the largest engineering firms in the country we have been enabled to make a series of measurements in a large friction testing machine, the results of which we here reproduce:—The test journal of the machine—which is of the Thurston type—is 3.8 in. diameter, giving approximately one foot peripheral per revolution. The length of the journal is 6½ in., and in all our experiments the load was 200 lb. per sq. in. The machine is provided with a revolution counter and a drum upon which the reading of the arc is automatically traced. The driving motor was operated by a variable speed controller, and all care was taken to ensure steady and constant speeds. The journal and bearing were thoroughly cleaned before each test by washing with toluol, and finally rotated against velvet pads to remove all superficial dust and moisture. The experimental temperature was kept between 60° and 64° F.

The values of the frictional coefficients calculated from the curves obtained directly from the machine are given in the table on p. 51 T.

By way of illustrating our point, four oils were chosen of identical viscosity and density but differing in composition thus:—

These results afford great support to the views expressed above, and, coupled with our experience in practical lubrication, about to be mentioned, confirm our explanation of the property of oiliness and open out a new and invaluable field in the manufacture of lubricating oil.

We should here mention that this principle of making lubricating oils by adding to mineral oils small quantities of fatty acids or substances which

lower the interfacial tension has been accepted by the Patent Offices in all civilised countries.

We should add a word here with regard to the possibilities of corrosion.

tendency, while one containing the lower members will possess a de-emulsifying tendency. This is a feature which we have tested by shaking oils and water at various temperatures for long periods of

Oil.	Viscosity at 60° F. Seconds Redwood.	Sp. gr., at 60° F.	Total acidity, calc. as oleic acid.	Mean temp. of expts.	Peripheral speed in feet per minute.	Quantity of oil used for test.	Arc.	Coefficient of friction.
A. Pure mineral	973	0.909	nil	62	11	5 c.c.	40	0.0084
B. 97% Pure mineral 1% Pale cylinder * 2% Com. fatty acids	973	0.900	1.9%	62	11	5 c.c.	25	0.0052
C. 80% Mineral 20% Olive	980	0.908	0.3%	63	11	5 c.c.	40	0.0084
D. 40% Mineral 60% Olive	970	0.907	0.9%	64	11	5 c.c.	35	0.0073

* Added to keep the viscosity constant.

As will be observed from the table above, all compounded oils which have been and are in daily use for years contain notable amounts of free fatty acidity, yet one rarely hears of any active corrosion.

In our case we add only very minute amounts of fatty acids, and the quantity is strictly limited and controllable. But where fatty glycerides are employed the amount of acidity which can form is potentially very large because hydrolysis is constantly going on, giving rise to the production of free acids.

During recent years a great deal of attention has been devoted to the study of the colloidal characters of the fatty acids, and it has been shown that while the lower members of the fatty acid group possess relatively little colloidal character, the higher members are highly colloidal in character. Donnan and Potts have shown that there is a gradation in these properties as one ascends the scale, lauric acid occupying a sort of intermediate position. Also the lower members of the series possess strong acid characteristics, while the higher members are very weakly acid. Now the fatty acids which occur in commercial oils are never pure chemical individuals, but are mixtures in varying proportions of a considerable number of fatty acids. Coconut oil, for example, is characterised by containing appreciable percentages of the lower members of the series, while rape oil rarely contains anything but the higher members.

It is only to be expected, therefore, that the behaviour of these oils will differ in accordance with the fatty acid groups which predominate in them, and it is possible to reproduce the capillary properties of any particular animal or vegetable oil by adding suitably chosen fatty acids to mineral oil.

Consider the case of a steam engine using saturated steam, where there is a tendency for condensation of water to occur in the cylinder and valves. It follows in such a case that the presence of a substance in the oil which lowers the surface tension against water will in such circumstances assist in the formation of oil films by enabling the oil to spread more readily or by overcoming the tendency of the water to wash the oil film off.

There is a certain type of lubricating phenomena to be considered where the oil is brought into contact with water and it is desirable that the oil shall either separate itself rapidly from the water (de-emulsification) or, conversely, that it shall mix or emulsify with the water.

Now the phenomenon of emulsification is dependent upon the colloidal properties of the oil, while de-emulsification is brought about by a greater concentration of hydrogen ions. Consequently one would expect the oil containing the higher members of the fatty acid group to possess an emulsifying

time, and to a great extent we have been able to substantiate this view as the result of experiments.

After the soundness of our theory was clearly demonstrated in the laboratory it remained for us to put it to the touch of actual practice to prove its real value in the world of engineering.

Not a single failure has occurred in practice of an oil or an oil "essence" made on the "germ process" as a reliable lubricating oil when used for the purpose for which it was supplied. The meaning of "oil essence" is explained later.

We use the expression "germ process" to describe the oil made by using one or more fatty or other acids with one or more mineral oils, because the world has been taught for generations to look upon acid as the deadliest enemy to good and safe lubrication. As the *germ* is the first principle of organic life, by analogy we call a suitable acid when dissolved in mineral oil the "germ," which gives to mineral oil its life and activity as a more perfect "instrument of lubrication."

We do not claim that a "germ process" oil is better for all conditions of lubrication, but for many purposes where lubrication depends upon the oil alone and not upon any mechanical means, such as pressure, to maintain a continuous film.

We have proved to our entire satisfaction that the addition of fatty oils to mineral oils for many purposes of lubrication is unnecessary and a waste of valuable material, and that for such purposes oils combining small percentages of suitable free fatty acid or acids with suitable mineral oils are at least equal to oils compounded on the old formulæ for those purposes. Therefore many of the old formulæ and specifications for compound oils are obsolete. Where the expression "compounded oils" is used, it indicates such old formulæ oils. Also, "mineral oil" indicates in many cases one or more than one mineral lubricating oil. "Fatty oil" includes tallow and other "fats" used for lubrication.

Gas engines.—It has always been considered that the addition of coconut oil to a mineral oil gave the best results. Refined rape oil or other fatty oil was also used in conjunction with coconut oil to the extent of about 5% of each; that is, about 10% of fatty oil, 90% mineral oil. Especially on large horizontal units such a compounded oil was deemed essential. For smaller units smaller proportions down to 5% total fatty oil to 95% mineral oil; though some small units apparently required heavily compounded oils.

So far as our business is concerned, "germ process" oils have entirely displaced such compounded oils for horizontal and vertical engines up to the largest units of both types.

Some gas engines run on "straight" mineral oil with good results, but roughly it can be claimed that ten units run on "germ process" oil to one on straight mineral.

Oil engines.—Compounded oils, and for some types "straight" fatty oils such as olive oil, have been considered essential for oil engines. For several types it was thought necessary to use a compound of one-third refined rape oil to two-thirds mineral oil. That oil has been entirely superseded by an oil with a slightly higher percentage of fatty acid than the average "germ process" oil for oil engines, but not over the maximum considered safe in practice. For other oil engines, land and marine, for which compounded oils were thought necessary, their place has been taken by oils made from one or more fatty acids with mineral oils of suitable quality.

The quality of the mineral oil with which the acid is blended is a very important factor in lubrication. The germ process gives to a mineral oil of fair merit that property lacking for some purposes; while it increases the lubricating value of a "good" oil, making it still better for many purposes. In both cases they become more economical.

Steam cylinder lubrication.—It is almost universally considered that for "perfect" lubrication of steam cylinders with certain types of valve gear (as one example, "Corliss"), and for engines working under certain conditions—say with much condensation in the cylinder—a compounded oil is essential.

"Germ process" oil incorporated in very small proportion with the correct mineral cylinder oil gives equally good results on engines with Corliss valves up to over 3000 h.p. working at 160–170 lb. per square inch pressure, superheated 480–500° F.; on horizontal engines with Corliss valves up to 750 h.p. up to 160 lb. pressure without superheat. Various mineral cylinder oil bases to correct "germs" in different but small proportions give thoroughly good lubrication on vertical and horizontal engines of many types, sizes, and pressures.

Oils for steam turbines, crank cases of vertical steam, gas, and oil engines.—The property most essential in oil for steam turbines, namely non-emulsification, is the one which largely governs successful crank-case lubrication in vertical engines. In such cases and in turbines water from condensed steam or from the cooling system falls into the crank case and gets "churned" as it is pumped round with the lubricating oil. For these conditions one has to know something about impurities in the water, as the water is the deciding factor. The "germ" must be carefully adapted to the water as well as to the oil, and the oil to the mechanism. Where one oil is used for cylinder and crank-case lubrication (say, of gas and oil engines) the "germs" can be balanced to give what for convenience can be described in a general way as a positive effect in the cylinder where extra capillarity is required, and a negative effect in the crank case where emulsifying is undesirable, and where the engine is steam, of the splash lubrication type, to give just enough emulsion and no more for its intended work in the cylinder, also in the crank case, where it must emulsify. The germs, for they are many, can be so adapted when one thoroughly apprehends their properties, to give perfect lubrication in all such cases.

Marine steam engine bearings—open type.—For a good heavy marine engine oil it has always been considered necessary, and is so to-day, to use from 10 to 25% thickened or blown oil—as a rule, thickened rape oil. This gives great viscosity, also very good "lathering" properties to the oil.

The standard specification for marine bearing oil for one of our semi-Government departments is a compound of about 20% "of fatty oil"; but the total fatty acid content must not exceed 1%. This has now been successfully replaced by "germ-process" marine-engine oil.

On February 5, 1918, we filed our patent* for oils made on this new process, and immediately its "publication or communication" was prohibited by the Admiralty, who carried out trials over many months on about fifteen ships of the mercantile marine, including a fair proportion of liners. The result was quite satisfactory.

At this stage we decided to supply the fatty acids in a form, which we term "essence," mixed with mineral oil and which can be conveniently used on board ship; about 2½% is added to the mineral oil as required. The result justified all claims. The consumption of mineral oil was considerably reduced, hot bearings were cooled, and thrust blocks were kept cool by the addition to mineral oil of suitable "germs." The trials were a complete success.

We think it desirable to say that it may not be advisable for oil users in general to buy fatty acids, to mix them in their oil and imagine all advantages mentioned will accrue. Suitable acids must be chosen for the purpose.

Conclusions.—We have shown (1) that fatty compounded oils are unnecessary for many purposes of lubrication; (2) that fatty oils are not essential for such work; (3) that fatty acids can entirely and completely displace fatty oils for those purposes.

Our thanks are here recorded to the following for invaluable assistance in our experiments and trials:—Prof. W. C. McC. Lewis; Messrs. Armstrong, Whitworth and Co., Ltd.; Corporation of Manchester Electricity Dept.; Mr. M. Shenton.

DISCUSSION.

Mr. L. ARCHBUTT said that he had made some friction tests with the process in the laboratory. It was obvious that under the conditions which obtained in an ordinary journal bearing running at a good speed, in which a film of liquid oil completely separated the journal from the bearing, fatty acids could be of no advantage, and that the only way in which they could act beneficially would be by improving the oiliness of the lubricant. The Thurston machine, as generally used, would not have measured anything but the fluid or viscous friction, but by running this machine at a very low speed and with a good load on the bearings a certain amount of contact friction had been obtained, and in all the tests he was about to describe the speed was 7 ft. per minute and the load about 270 lb. per square inch. A few preliminary tests were made with "Tonicol," containing about 25% of free fatty acid, and these showed that 2½% of "Tonicol" mixed with mineral oil lowered the coefficient of friction to the same extent as about 10% of ordinary commercial rape oil. Further tests had been made with a paraffin-base oil of practically the same viscosity as rape oil at 60°–65° F., the temperature in all the tests. In each series the machine had been run with the mineral oil alone until the friction had become steady; then, without stopping the machine the oil had been changed to a mixture containing fatty acids prepared by himself from rape oil, and then a final check test was made with mineral oil alone. The result of the first series was as follows:—

	Mineral oil.	Rape oil fatty acids.	Friction coefficient
1.	100.0	oil.	0.0066
2.	99.5	0.5	0.0049
3.	99.0	1.0	0.0045
4.	98.0	2.0	0.0042
5.	100.0	nil.	0.0066

This was conclusive. In further tests nearly 80% of perfectly neutral rape oil, specially prepared, had been required to reduce the friction as low as 2% of rape oil fatty acids; 100% of the rape oil had actually given a rather higher average friction, but this small difference was within the limits of the error of the method.

* Eng. Pat. 130,677; see this J., 1919, 674A.

The results were as follows:—

	Mineral oil.	Neutral rape oil.	Friction coefficient.
1.	100	nil	0.0066
2.	90	10	0.0065
3.	80	20	0.0062
4.	60	40	0.0053
5.	40	60	0.0047
6.	20	80	0.0041
7.	nil	100	0.0043
8.	100	nil	0.0062

Finally, another series of four tests had been made, comparing the mineral oil, commercial rape oil, and neutral rape oil, and the results were as follows:—

	Oil	Friction coefficient.
1.	Mineral oil	0.0078
2.	Neutral rape oil	0.0050
3.	Acid rape oil (2.4% fatty acids)	0.0045
4.	Mineral oil	0.0078

These results appeared to him to prove the authors' contention as regards the friction-reducing value of free fatty acid to be perfectly sound, but he could not agree that the lowering of the interfacial tension between oil and water, or even between oil and mercury, though very interesting and important, was a sufficient explanation of the nature of oiliness. The authors' own experiments showed that the interfacial tension between nearly neutral rape oil and water was almost as high as that of mineral oil, and much higher than that of acid rape oil. Yet his (Mr. Archbutt's) experiments showed that neutral rape oil when mixed with mineral oil lowered the friction, and there was very little difference between the coefficients given by neutral rape oil and acid rape oil. Mr. Deeley, in his recent communication to the Physical Society, had expressed the opinion that oiliness was a chemical property, and that the unsaturated molecules of the lubricant united with the solid metal surface and formed a new surface which opposed less resistance to shear than the unlubricated metallic surface. The remarkable papers by Langmuir and Harkins strongly supported this view. Langmuir said: "Since energy must be expended in breaking apart a solid, the surfaces of solids must contain more potential energy than do the corresponding number of atoms in the interior. Since the potential energy is probably electro-magnetic energy in the field between the atoms, the interatomic forces are more intense on the surface than in the interior. This intense field (unsaturated chemical affinity) is one of the causes of the phenomena of condensation and adsorption" (J. Amer. Chem. Soc., 1916, 38, 2293), and in a later paper, after describing a number of experiments, Langmuir said: "These results afford the strongest kind of confirmation of the theory that the spreading of films on surfaces is determined by the shapes of molecules and the relative activities of the different portions of the molecules" (*ibid.*, 1917, 39, 1881). "Consider first the adsorption of a liquid containing active groups. The molecules will become orientated and will pack into the surface layer in much the same manner as in the case of oil films spread on the surface of water" (*ibid.*, 39, 1901). W. B. and F. K. Hardy (Phil. Mag., 1919, 38, 32) had come to a similar conclusion. They said that "the function of a lubricant is to reduce the energy of the surface, and thereby to reduce the capacity for cohesion and the resistance to slip when two composite surfaces are applied the one to the other." All recent work pointed to the fact that it was the chemically reactive and unsaturated constituents of lubricants which promoted oiliness, and that they did so by forming new composite films on the surfaces lubricated, with lower surface energy and opposing less resistance to shear, and the great activity of free

fatty acids was quite in accordance with this theory. Referring to the statement in the paper as to the occurrence of hydrolysis and formation of free acids in oils, he did not think much hydrolysis took place in an ordinary bearing, but it did in a steam cylinder. He agreed that so long as the quantity of free fatty acid in a lubricating oil did not exceed 1 or 2%, which was as much as was necessary, as his own tests had shown; $\frac{1}{2}$ % did most of the work, and an addition up to 2% did not make a very great difference; this small quantity of fatty acid could not do any possible harm and was far more useful than a larger quantity of fatty oil, besides the saving it effected. A little misconception might arise from the statement attributed to him that 1% of free fatty acid lowered the coefficient as much as did 60% of pure rape oil. That was not commercially pure rape, but a special neutral rape oil which he had made in the laboratory, and which was not an article of commerce. He was struck by the fact that 80% of mineral oil and 20% of olive oil made no difference to the friction coefficient, and that 60% mineral oil and 40% olive oil only lowered it to 0.0073. He wondered what that olive oil was. The sentences quoted in the paper from the communication which he himself had made to the Physical Society needed the context, because what he meant was that, comparing acid rape oil with neutral rape oil, there was not very much difference, so that the effect of the free fatty acid in the rape oil was not nearly so great as when it was added to the mineral oil.

Mr. ARNOLD PHILIP agreed with Mr. Archbutt that the authors had not succeeded in showing what oiliness was. Oiliness could not be explained as being merely due to the wetting of the rubbing surfaces by the lubricant, because glycerin, which had a very similar viscosity and density to that of some oils, would certainly wet ordinary bearing surfaces, but as a lubricant it was, of course, valueless. The property of "oiliness" possessed by lubricants, excluding the views to which Mr. Archbutt had referred, had up to the present only been measurable by the results obtained when using the lubricant on machinery under ordinary running conditions or by special tests made with mechanical oil testers, such as that of Thurston. The authors' results, however interesting, were not referred to these standards, and as an explanation of oiliness were, he considered, meaningless. General commercial practice had shown for many years past that the admixture of small amounts of fatty oils with mineral oils did distinctly improve the mineral oil for many purposes. He believed that this had been stated to be due to the formation of metal soaps on the bearing surfaces. In any case he had this explanation very strongly indicated in his own practice by the fact that some fourteen years ago difficulty had been experienced with machinery running at low temperatures, due to solidification of the sperm oil which was used as a lubricant. To remedy this a pure non-freezing mineral oil had been substituted for the sperm oil. The result had been that the mineral oil had come away from the bearings full of turbidity, caused by flakes of solid material, which consisted of oleates and stearates of iron and copper stripped from the bearing surfaces. These had been formed by the use of the sperm oil in the first place, and this solid coating of the metal bearing surfaces had afterwards become displaced and washed out by the mineral oil subsequently used. As this mineral oil was a perfectly clear, water-white liquid the presence of the flakes of oleates and stearates in it after use had been very evident. After the stripping of these heavy metal soaps from the bearing surfaces by the mineral oil it had been found that the friction had increased, but whether this was actually due to the removal of the stearates and oleates was not quite clear. Some eight or ten years ago he had

had the important function of the free fatty acid in such lubricants still further impressed upon him by the manufacturer of a fatty oil, for making blended or compounded fatty and mineral oils for lubricants, who had informed him that he always made an oil containing a large percentage of fatty acids. In fact, he spoke of the use of this acid fatty oil as being a special secret, and stated that it gave particularly satisfactory results for making blended lubricating oils. Consequently, when about two years ago the proposal of the authors for using mixtures of fatty acids and mineral oils had been referred to him by the Admiralty, he had approved it and reported that it appeared, on the face of it, to be good not only on account of the saving in fatty oils which it effected, but also because the use of compound mineral oils and fatty acids appeared technically correct for certain lubricating purposes. What the authors had done which was novel was to use a fatty acid as distinct from a fatty oil for blending with mineral oils. He deprecated the use of the term "germ" as applied to the process and also the use of the word "essence," both of which were misleading.

In a written communication PROF. F. G. DONNAN pointed out that a great deal of the matter brought forward apparently as novel by the authors had been already discussed and elucidated by himself. For example, he had shown experimentally so long ago as 1899 (*Z. Physik. Chem.*) that the interfacial tension between a fatty or hydrocarbon oil and an aqueous solution was dependent mainly on (a) the presence of alkali in the water, (b) the presence of free fatty acid in the oil. In the paper referred to the quantitative dependence of the interfacial tension on these two main variables had been experimentally measured, and the cause of these phenomena fully elucidated. Many other important interfacial tension and concentration effects had been investigated in later papers by his pupils (work of Lewis, Potts, Barker, Ellis, Powis) working under his direction.

MR. T. THORNTON asked if the authors had used aqueous emulsions as lubricating agents. The function of a lubricant was to keep metal surfaces separate with as little expenditure of energy as possible, and if an aqueous emulsion were used an effect was obtained similar to that of a ball bearing. It gave the superiority of a ball bearing over an ordinary friction bearing. Instead of having a reduction of about 60% by introducing fatty acids, an aqueous emulsion containing about 25% mineral oil would reduce the expenditure of energy by at least 85%; e.g., when using 100 amperes at a known voltage with a full mineral oil and then turning over to an aqueous emulsion containing 25% of some mineral oil, the current expenditure had fallen to 15 amperes. Such an emulsion could be prepared by homogenising a mineral oil and soap solution containing 2½% of ordinary soft soap. These emulsions had been used in certain special cases with a good deal of success for something like twelve months on fairly heavily loaded bearings at medium speeds.

DR. W. R. ORMANDY said that it seemed impossible to draw the conclusion that interfacial tension was the basis of what was called "oiliness," because certain experiments with an oil containing free fatty acids as against water gave a certain result which was more or less directly comparable with the results obtained in practice on a metallic surface, and it would have been wise to have tried the experiment of oils in other liquids, with which they were immiscible in order to see in the first place if the interfacial tension between the other liquids bore anything like the same ratio to the results on a metallic surface. He thought that Mr. Archbutt had adequately explained the bearing of Langmuir's theory of surface energy in its

relation to the question of lubrication. Langmuir would contend that on the surface of the metal there were certain free fields, and these free fields or residual valencies could attract a certain number of fatty acid oil molecules until they were saturated. Langmuir had proved by many experiments that once they had satisfied all the free valencies, as it were, on the surface and had got it covered with a layer one molecule thick, the attraction afterwards did not count, and any addition to the oil produced a very small effect. Similar results had been obtained by Hardy, who had shown that a layer one molecule thick was sufficient to prevent adhesion of one glass surface to another. Therefore if there were sufficient of the fatty acid, or whatever material it was, adsorbed on the metal surface to satisfy the valencies of that surface, any further addition would produce a comparatively slight effect. That was borne out by Mr. Archbutt's first series of experiments.

PROF. J. S. S. BRAME, in referring to the work which had already been done on this subject, particularly by Archbutt and Deeley, and described in their papers before the Physical Society, said that Messrs. Hardy had carried out experiments on the static friction with different fatty acids ranging from those of low molecular weight to high molecular weight, and it was shown, not only in the case of these fatty acids, but in the case of alcohols and amines, that increase of molecular weight was associated with a progressive decrease in static friction. That seemed to have a very important bearing on the question under discussion, and he asked whether the authors found that there was any relationship between the molecular weight of fatty acids and the friction of the hydrocarbon oil mixture. Did the authors find that a saturated fatty acid of approximately the same molecular weight as an unsaturated fatty acid had the same effect? In one of the tables the interfacial tension with water between olive oil and coconut oil containing approximately the same amount of fatty acid was practically the same, viz., 72 to 68. The Hübl iodine absorption number for the fatty acid from olive oil was about 90, and for the fatty acid from coconut oil it was 9, which suggested that perhaps there was not much difference between the action of a saturated and an unsaturated fatty acid. Was there any connection between the action of a given fatty acid with different types of hydrocarbon oils where there was considerable variation in the amount of the unsaturated hydrocarbon present—for example, the average shale lubricating oil, which was rich in unsaturated hydrocarbon molecules, and a "straight" petroleum lubricating oil, where the proportion of unsaturated molecules was very much less? He agreed with Mr. Archbutt and Mr. Arnold Philip, however, in thinking that the authors carried the matter very much further towards arriving at a solution of what "oiliness" really meant.

MR. A. A. DRUMMOND said that some years ago a letter had appeared in "The Engineer" dealing with the corrosion of steel balls through the action of lubricating oils, including mineral oil and fatty oils, like olive oil and lard oil. In no case, after six months, had there been any sign of corrosion except with castor oil, and this had shown quite appreciable corrosion visually, particularly under the microscope. Not only had castor oil shown this and differentiated itself from the others, but the same difference had been noticed in the case of the fatty acid of castor oil as compared with the corresponding acids of the other fatty oils. Perhaps the author could offer some explanation of the difference exhibited.

MR. SOUTHCORBE, in reply, said that they were not anxious to make out a theory. They had

observed certain differences in interfacial tension of commercial lubricating oils against water, and then stated the further fact that the presence of fatty acidity lowered the frictional coefficient, and they supported that by a further fact that the presence of this fatty acidity also lowered the tension against mercury surfaces. Even if residual valency were the explanation it would manifest itself in the same way, *i.e.*, it would cause a lack of abruptness of the transitional layer and that diminution in the abruptness of the transitional layer would manifest itself as a lowering of the interfacial tension, and therefore it was only a question of which side one looked at the problem from. With regard to residual valency, unsaturation was the essence of Langmuir's theory, unsaturation in the sense of the presence of matter of which the valencies were fully saturated so far as ordinary chemical reactivity went, but which had probably some unsaturated linkages not satisfied. The hydrocarbons which constituted mineral lubricating oil were more highly unsaturated than were any of the compounds of the fatty glycerides, taking saturation in the chemical sense. From the experiments of Mabery and others it was seen that the mineral oils which had high viscosity and were very much used as lubricants were characterised by very high unsaturation. In the two oils dealt with in the paper, and from Mr. Archbutt's experiments, he suggested that the one which Mr. Archbutt called mineral oil, 100, was more highly unsaturated than was the pure rape oil, so that if the view point of the authors had not been proved, he did not think they were very much further advanced from a practical point of view by the Langmuir idea. Mr. Arnold Philip had suggested that the effect of the fatty acid was to form metallic soaps. If this were the case in any short period of time then it must be a definite proof of the adsorption idea. The case which Mr. Philip had brought forward was not parallel. He had spoken of a bearing running on sperm oil and changing that for a mineral oil. The sperm oil might have been in the bearing for a very long period and would necessarily have corroded the bearing to a certain extent. On the other hand, the fact that the coefficient of friction was lowered instantaneously by the addition of fatty acids, as shown by the authors' figures and confirmed by Mr. Archbutt, was proof that that had nothing to do with wholesale soap formation. There must be adsorption which would secure an almost instantaneous lowering. He could not agree that the example given of glycerin disproved the "wetting" view. Glycerin was quite a good lubricant, but its hygroscopic properties made it commercially useless because in practice it rapidly becomes an aqueous solution. It was true that Prof. Donnan had shown how to determine the adsorption on surfaces of fatty acids in oils in alkali solution, but the object of his paper was to take a series of fatty acids, from acetic to stearic, and determine the interfacial tension against alkali solution by the drop pipette, and he (Prof. Donnan) had succeeded in showing that as the series was ascended the surface tension became very much lower, but he was not concerned with a diminution in interfacial tension against water. Prof. Donnan's results were of a totally different order of magnitude. His drop number went up from, say, 100 to 200, 300, and 400, against dilute alkaline solutions, which was what he was measuring. Donnan's work did not refer to the problems of lubrication. It was true that the drop pipette method had been applied by Prof. Donnan and his collaborators, but what the authors were claiming to show was that such an instrument could be used in the examination of an oil. They were glad to take this opportunity of stating that Prof. Donnan's work on the drop pipette had been inspiring and of value. Mr. Thornley had spoken of aqueous emul-

sions of lubricating agents. He (the author) did not know the conditions under which these emulsions had been employed, although their use was not new. The only point there which would interest him was the question of the "wetting." Such emulsions were generally pumped under forced feed, and it did not concern the present paper. In reply to Prof. Brame, they had not done anything to show the variation of the frictional coefficient with the molecular weight of the acid. They had, however, carried out a series of experiments with regard to emulsification and de-emulsification which would be published shortly. He did not think that a research as to the effect of degrees of saturation would be very fertile, because, as he had already pointed out, there was equal unsaturation in a great number of the mineral oils themselves possessing high frictional coefficients as compared with the unsaturation of the fatty glyceride. In reply to the other point raised by Prof. Brame, there was a very distinct influence on the properties of the final lubricants by adding different fatty acids to any given mineral oil, and there was also a different result with a compounded oil obtained with one given series of fatty acids with different hydrocarbon oils. With regard to Mr. Drummond's query on the question of corrosion of steel balls and the effect of castor oil, he did not think that came within the scope of the paper. The only thing he could suggest was that with castor oil acids were formed by oxidation which would be very dangerous from the corrosion point of view. These, however, were not the acids used in compounding lubricating oils.

Professor C. V. BOYS, in a letter to the Scientific and Industrial Research Department, writes as follows:—

"I notice that the conclusions arrived at by Messrs. Wells and Southcombe depend on the determination of oil-water surface tension, or rather of comparative values, by the method of counting of drops. As a general proposition I very much doubt the conclusion that the number of drops in a given volume is inversely as the surface tension, although it may be for some particular pair of liquids or with a particular difference of density. The mere fact that the difference of density of the two liquids, which is one of the operative factors in determining the drop size, is not included in the statement and appears to be ignored is alone sufficient to raise very serious doubts; but quite apart from this the very complicated conditions which determine the moment of instability or the breaking off of a drop themselves appear to me to be incompatible with any such convenient conclusion. I say convenient conclusion because if the method were correct in principle it could not be surpassed in ease of application.

"My object is not destructive criticism, but a desire to propose an absolute method of determining the actual surface tension of the water-oil surface in CGS or other definite units. It seems to me of the first importance as the conclusions of the authors are based on comparative measures of surface tensions that the method of making the measures should be above suspicion; further, mere comparative measures, even if correctly comparable, are less desirable than absolute measures.

"Now, in all methods of finding drop size by allowing liquid to enter the drop, however slowly, until it breaks away, the hydrostatic pressure of the liquid at any level within the drop is unknown, but the following relations hold. If P is any point on the surface of the drop (which is a figure of revolution) and $P a b$ a normal to the surface, then if the hydrostatic pressure in the oil at the level P exceeds that in the water at the same level by the amount p dynes per sq. cm., t the surface

tension in dynes per cm. and p are related thus:—

$$p = t \left(\frac{1}{P_a} + \frac{1}{P_b} \right)$$

a is the point where the normal cuts the axis of revolution, and b is the centre of curvature of the profile of the drop at the point P . At a lower point P' the same is true, but here the difference of pressure is less by the amount (density of water—density of oil) $\times PM \times g$. All distances in cm. and g in this

latitude 981. As the drop grows there comes a time when the differences of hydrostatic pressure and the lengths Pa Pb in different parts of the drop are becoming incompatible, and instability results. The breaking depends on differences of hydrostatic pressure within the drop as compared with the surrounding water which determine the rupture. The actual hydrostatic pressure is not known, and its determination by elimination among the measurements of Pa Pb at a number of points P would be very tedious and inaccurate. In a paper* 27 years ago I showed how these forms may be drawn by a device there illustrated with far greater speed and accuracy than had hitherto been possible, but all methods of determining surface tension in slowly growing drops which are allowed to grow until they break away have the disadvantage that there is nothing easily tangible or measurable except the number. In the first edition of my book on soap bubbles I showed a number of photographs, 23 in a cycle, of a growing drop in a water surround, but the coming of instability led to movements of such rapidity even in these large and slow moving drops as to indicate how hopeless measurements at the critical phase would be.

"What I want now to suggest is that the surface tension should be determined absolutely by direct measures of the hydrostatic pressure within and without at the highest point of the drop. This point has the advantage that the contact here of the circle of curvature is a contact of the third order, and the radius of curvature r can at this point be determined with an accuracy far greater than the Pa and Pb referred to above. The Pa and Pb become the same at this point, and thus the right-hand side of the equation becomes $2t/r$. The method of finding r and p and thence deducing t will appear after the construction of the proposed apparatus is clear.

"This consists of a tube of the form shown, which may be held in a micrometer vertical slide (not shown) so that it may be moved gently through known very small amounts vertically. The tube contains some of the oil to be tested, and the stop-cock is used to stop all movement of oil when once it has reached the drop-forming surface and during the time that it is being immersed in the water and secured to the micrometer slide. The water is contained in a cell with plate glass sides through which all that is happening may be observed. The shape and radius of curvature of the drop will ultimately be determined by means of an enlarged photograph taken with a lens of, say, 4 in. focus, and in order that the scale of magnification may be known two points a definite distance apart attached to the drop end of the tube are photographed at the same time. The straight line joining them is exactly central. It would be advisable also to make the points at the same level as the drop end of the glass tube as will appear. All photographs of drops and other measurements made with a cathetometer are done when the stop-cock is open and equilibrium is attained. Then $w \times$ density of water $\times g$ is the hydrostatic pressure of the water at the level of the top of the drop; $o \times$ the density of the oil $\times g$ is the hydrostatic pressure of the oil in the drop at the same level, and this product is the greater of the two when the drop shows any convexity. They are equal when the oil surface is plane. Calling this difference p , and r the radius of curvature obtained from the enlarged photograph $p = 2t/r$.

"Now in order to make an experiment the tube is placed in position with the stop-cock closed, and is moved vertically until w and o are as nearly as possible inversely as the respective densities. Then, all being quiet, the stop-cock is opened. The surface of the oil at the drop orifice should be very slightly if at all curved. The slide is moved until as far as the eye can tell the surface is plane. If the surface reflects light this can be done with very great accuracy. w and o measured at once give the density, and a thermometer in the water the temperature. Now the tube is raised a small known amount by the micrometer screw of the slide, and the oil surface becomes slightly convex, and the curvature is determined by an enlarged photograph. w and o may again be measured with the cathetometer, but the micrometer screw will give a more accurate measure, for it gives a direct measure of the lifting of the apparatus. This gives the increased effective hydrostatic pressure of the oil subject to two small corrections. (1) The water level falls by an $\frac{1}{m}$ part of the elevation, m being known from the area of the free water surface and the area of the tube and stop-cock stem intersected by the water surface. The oil depth is reduced by the height of the drop, which can be got from the photograph of the drop and two points, and also by the fall of oil in the tube due to the small content of the drop. These may be calculated with great accuracy, or with a good cathetometer w and o may be directly measured each time.

* "The drawing of curves by their curvature." Phil. Mag., 1893, July, p. 81.

"A series of photographs and measurements of drops successively more developed give a number of values of surface tension in absolute measure, and the consistency of these will give a measure of the accuracy with which the determination is made.

"I am not sure what is the best diameter of the drop end of the tube. The authors have probably found this already by experiment. The diameter has to do with the possible development of the drop shape, and extremes either way give less convenient forms for the purpose of measurement.

"The above observations are directed solely to the experimental operation of finding the oil-water surface tension. I am not discussing the propriety or utility of this determination in relation to journal friction.

"If the water and oil were absolutely immiscible and uncontaminated either by the other it would be a matter of indifference whether a water drop were formed in a surround of oil hanging downwards or an oil drop were formed in a surround of water hanging upwards: the surface tension would be the same, and the sizes and forms of the drops for the same p would be identical. If, however, as is probably the case, there is some degree of miscibility and contamination, the conditions might well not be the same, if so little water and much oil are different materials from little oil and much water. If there is a difference, I do not know which measure would more truly give the quantity that the authors seek to find. Further, I am not satisfied that there is justification for using the water-oil surface tension any more than the oil-air surface tension. However, the real object of this letter is not to go into this question of justification, but to give the best help I can in a class of experiment in which I have a good deal of experience."

MR. JOHN ALLAN IN THE CHAIR.

THE ACTIVATED SLUDGE PROCESS OF SEWAGE PURIFICATION—LARGE SCALE OPERATION.

BY EDWARD ARDERN, D.S.C., F.I.C.

In view of the satisfactory results obtained from the experimental investigation of the activated sludge process as applied to the treatment of the sewage received at the Withington Sewage Works (Chorlton-cum-Hardy) of the Manchester Corporation, which were described in 1916,* a large-scale continuous-flow demonstration plant, designed to treat 250,000 gallons of sewage per day, was installed at these works in October, 1917, with the view of studying the process under working conditions.

In the present communication it is proposed to give a description of this installation, together with a general account of the results obtained during the two years it has been in operation.

The earlier investigations were practically confined to the operation of the process on the "fill and

draw" system, in which both the aeration of the sewage and settlement of the sludge were effected in the same vessel. There are several objections to this intermittent method of operation, chief of which are the fall required for the discharge of the clarified effluent and the constant attention involved.

In translating the process to the working scale, therefore, the plant was so designed as to allow of its continuous operation, which not only obviates the above-mentioned disadvantages, but at the same time renders the process more adaptable to the treatment of the fluctuating flows of sewage received at the disposal works.

The plant, which was designed by Messrs. Jones and Attwood, Ltd. (Stourbridge), in consultation with the author, occupies one-third the area of one of the existing sedimentation tanks, and may be described as follows:—

Aeration Chamber.

The aeration chamber, 100 ft. long by 22 ft. wide (overall) and 6 ft. deep (water level to diffuser), is divided by four longitudinal walls so as to form a channel 4 ft. wide and 500 ft. in length. Its capacity is 55,000 galls. The floor of this channel is constructed on the ridge and furrow system, the ridge having a slope of 35° with the horizontal. Aeration is effected through rows of diffusers placed in the furrows transversely to the flow of sewage. The diffusers are each 1 ft. square over all, so that their total area is approximately one-seventh of the aeration tank area. The ratio of the net diffusion area to total tank area is 1:10. An overhead system of air pipes is provided, and the air is admitted to the diffusers through a series of down pipes, arranged so that one pipe serves two diffusers. Valves are attached to the various distributing pipes, so that the air supply may be regulated and distributed uniformly.

Settlement Tank.

Separation of the activated sludge from the purified effluent is effected in a deep pyramidal tank, 23 ft. 6 in. by 26 ft. 6 in. in plan, and 23 ft. 6 in. deep from water level to apex of tank. The sides of the tanks have a slope of 60° to the horizontal.

The mixture of effluent and sludge is admitted to the centre of the tank through a 15 in. pipe within a guard chamber 6 ft. square, and discharges into a deep wrought-iron bucket suspended from the top of the pipe. This arrangement was designed by Mr. W. Clifford with the view of dissipating the energy of the incoming flow by the creation of eddies within the guard chamber, and thus to produce, as far as possible, a quiescent condition at the bottom of the guard chamber, and so allow of efficient settlement of the sludge. The final effluent leaves the tank over four corner peripheral cells. The total capacity of the settlement tank is 27,000 galls.

Sludge Circulation.

The sludge is discharged by hydrostatic head from the apex of the tank through a 6 in. pipe to a separate chamber fitted with diffusers, from which it is returned by air lift to the aeration chamber.

Surplus sludge is either pumped from the return sludge chamber on to drainage beds, or is removed by siphon to the existing sludge well and discharged mixed with the sludge from the sedimentation tanks on to the land.

Air Supply.—For this purpose a belt-driven Reavell compressor, designed to deliver 500 cub. ft. per minute at anything up to 15 lb. pressure is employed. The machine is driven by a disused tandem high-pressure air compressor, which has been converted into a steam engine by removal of the air piston and the provision of a new driving pulley.

* This J., 1917, 65—68.

Flow measurement.—A Lea flow recorder has been installed at the exit end of the plant, and the purified effluent is measured as it passes over one or more V notches. Four such weirs are provided so as to obtain an accurate record of considerable variations in actual flow.

Air consumption.—This is measured by calculations from piston displacement and engine speed.

The sewage prior to treatment in this plant is screened and flows through two detritus tanks, the combined capacity of which allows of 40 minutes' detention in normal dry weather.

When the plant was first brought into commission a flow of sewage was passed through at the rate of 100,000 galls. per day for fifteen hours out of the twenty-four (6 a.m. to 9 p.m.). During the rest of the day the flow was shut down and the contents of the installation circulated by means of the air-lift placed in the sludge pit connected with the settlement tank. In this way satisfactorily purified effluents were obtained during the period required for the production of an active sludge.

As the amount of sludge increased the volume of sewage treated was gradually raised without interfering with the degree of purification effected.

When the sludge present in the aeration chamber had increased to 20% by volume, measured after one hour's settlement, the flow of sewage was stopped and the contents of the plant circulated as previously described until the liquor was free from ammonia. At this stage the activity of the sludge was such that the installation was capable of treating 100,000 galls. of sewage per day with practically complete nitrification. During the next few days the flow of sewage was gradually increased from 100,000 galls. to 250,000 galls. per day, with the maintenance of a high degree of nitrification. In this manner an adequate supply of activated sludge was produced in rather less than a month, to enable the plant to be brought into full and regular commission.

Following are a series of average results over various periods, which demonstrate the capacity of the plant under varying conditions:—

110,000 galls. to 250,000 galls. per day (average 150,000).

It will be seen that the effective capacity of the plant is well above the 250,000 galls. per day for which it was designed.

The figures given for the results obtained when treating the sewage at the rate of 500,000 galls. per day cover a period of eight weeks continuous operation at this rate. Towards the end of this period the sludge showed signs of diminished activity, which necessitated a return to a lower rate of flow. It is, however, evident that the plant is capable of operation at this high rate for limited periods when the sewage is diluted by appreciable rainfall without interfering with its efficiency.

The chief characteristics of the effluents obtained are their remarkable clarity, the ease with which they pass the Royal Commission suggested standard of 20 parts dissolved oxygen absorbed per 100,000 after incubation with aerated water for five days at 65°, and their low bacterial content, which averages about 20,000 organisms per c.c. (G.P.B.), which represents a reduction of 98% on that of the sewage treated.

Special attention has been paid to the amount of sludge produced in the process. Two typical determinations are given below:—

Sludge Production.

	1919.	
	Sept. 18th to 30th	Oct. 1st to 31st
Volume of sewage treated (gallons)	3,360,000	6,310,000
Volume of surplus sludge (galls.) per million gallons sewage treated	23,200	35,300
Water content of sludge	99.4%	99.6%
Dry solids (lb. per million gallons sewage flow)	1,342	1,348

The above volumes of sludge are the quantities actually removed from the plant (during the respective periods) by siphon from the sludge chamber, connected with the settlement tanks, during the operation of the plant.

Sludge of increased density and consequently reduced volume could be obtained if the operation of the plant was interrupted during sludge removal. Where actual volume of sludge is a deciding factor

Results in parts per 100,000.

	Dry weather sewage.				Wet weather sewage.			
	Maximum air supply*		Low air supply†		Low air supply.*			
	Sewage†	Effluent	Sewage†	Effluent	Sewage†	Effluent	Sewage†	Effluent
Four hours' oxygen absorption	3.53	0.66	3.90	0.73	2.53	0.67	2.93	0.60
Free and saline ammonia	3.00	1.53	2.66	2.31	1.94	1.63	2.11	1.54
Albuminoid ammonia	0.59	0.10	0.66	0.115	0.46	0.13	0.53	0.11
Nitrate and nitrite (as NH ₃)	—	0.64	—	0.14	—	0.37	—	0.34
Dissolved oxygen absorption	—	0.93	—	0.93	—	1.00	—	1.34
(Royal Commission test)								
Suspended solids	18.0	3.0	—	—	13.0	3.4	—	—
Vol. of sewage treated (galls. per day)	250,000		250,000		340,000		500,000	
Air consumption (cub. ft. free air per gallon of sewage)	1.7		1.0		0.8		0.0	

* Uniform rate of flow.

† Flow roughly proportional to rate sewage is received.

† Screened and detritus-free sewage.

The volume of sludge employed in the aeration chamber has varied from 15 to 30% measured by volume after 1 hour's settlement.

The figures for air consumption include the volume required for working the air lift, returning the sludge from the settlement tank to the aeration chamber, which amounted on the average to about 10% of the total volume employed. The volume of thin sludge circulated by the air lifts varied from

in respect of its disposal, ancillary settlement tanks should be provided whereby a reduction in volume can readily be effected. These two periods are given as illustrating the great variation of the density of the sludge in circulation, and this question of sludge volume will be referred to later.

In connection with this important question of sludge production the following information is of interest in regard to the respective suspended solid

content of the screened and detritus-freed sewage treated and of the effluent yielded.

Suspended solids parts per 100,000 (excluding colloids)	Average Total	Sept. 18th to Oct. 3rd 1919.	
		Mineral matter	Organic & volatile matter
Sewage	12.7	3.5	9.2
Effluent	1.1	0.4	0.7
Difference	11.6	3.1	8.5
Equivalent to lb. per million gallons	1,160	310	850
Dry matter calculated from sludge production	1,346	306	1,040

Judging from these results, the sludge produced (dry matter) is greater than is accounted for by the difference between the suspended solids contained in the sewage treated and in that passing away in the effluent.

It would thus appear that any resolution of the sludge by carbonaceous fermentation is considerably more than counterbalanced by the solid matter resulting from the flocculation of colloidal solids and the growths of numerous higher organisms.

Attention should be called, however, to the difficulty of obtaining over a long period a true sample of such a heterogeneous mixture as sewage, and it is possible that some of the grosser suspended matters escape sampling.

The sludge as it is withdrawn from the plant is dark greyish brown in colour and possesses a not unpleasant earthy odour, something like that of exposed seaweed. It is quite flocculent and has the appearance of an iron or alumina precipitate. Its density varies very considerably, but it may be reduced to a fairly constant water content of 98.5% by settlement alone. When the percentage of water is reduced to 90% by treatment on drainage beds, centrifugal action, or pressure, the sludge is no longer fluid, but is of the consistency of a fairly stiff jelly, due to its gelatinous nature.
